Address

MENTAL ALIENATION IN WOMEN AND ABDOMINO-PELVIC DISEASE

CHAIRMAN'S ADDRESS IN SECTION ON OBSTETRICS AND DISEASES OF WOMEN AT THE SIXTIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, 1909

W. P. MANTON, M.D.
DETROIT

At the opening of this Section for 1909 I desire to express to you my sincere appreciation of the honor which you have done me in continued confidence during the past years. It comes to few men to have served continuously a section in every capacity within that Section's gift, and now in relinquishing active office after so long a period, I feel that my being here is due rather to your kindly tolerance than to anything that I may have done to merit it.

This Section, from the small and inconspicuous gathering which annually took place before the reorganization of the Association, has now become a factor in the world's work, and its transactions present a volume on special subjects in scientific value second to none. The papers and discussions emanating from this Section have greatly enriched the literature of gynecology and obstetrics, and it only remains for us to maintain the high standard which has been reached in our deliberations.

At the turn in the lane we sometimes pause to look back along the way that we have come, observe the windings of the path, the roughness of the ground and the hard places that have been crossed, and, perhaps, with Stevenson, we "draw back and shade our eyes before the picture dawns on us in full breadth and outline."

After more than a quarter century of active interest in the nervous and mental disorders of women associated with pelvic disease, I may, perhaps, be permitted at this time again to refer briefly to a subject regarding which I have spoken much, and review some of the things historical and some which have passed under observation during the period mentioned, and for which I may claim, at least in some degree, responsibility.

In his book on "Mind and Body" Alexander Bain states that "the entire bodily system, though in varying degree, is in intimate alliance with mental function. To confine our study to the nervous substance would be to misrepresent the connection, and the knowledge of that substance, however complete, would not suffice for the solution of the problem." But this idea was almost as old as the hills when Bain wrote the wo[illegible] quoted, and was familiar centuries before the Cl[illegible]ra, for Hippocrates and his followers unders[illegible]

an al
train, anx
-fatigue and

called "sympathetic insanities," while at a nearer time the man out of the tombs exemplified, if he did not put into words, a fact now familiar to all, the relation of somatic conditions to the delusion of the insane.

Acting on the material facts which medicine had separated from the dim uncertainties of philosophy and metaphysics, the ancients appear to have cared for and respected their mentally deranged with a greater solicitude and consideration than was accorded the insane by subsequent generations, for during the Middle Ages, dark ages indeed for the unfortunates who bore the blotted brain, the subject of mental disorder was looked on as a sore on the fair face of humanity and a shame and disgrace to both family and state. Cruelty and brutality obtained to extreme degree, and the mentally sick, like Shimshon of old, was often the butt of the jester and forced to make sport for his hardened keepers and a degraded populace.

Such was the status of the insane up to the latter part of the eighteenth century, when Pinel, most courageous and enlightened of his time, struck off the fetters from the inmates of Bicêtre (1792) and inaugurated a new era in the treatment of mental disorders. From this time on, increasing interest in the welfare of the insane developed, the study of psychiatry received an impetus and a knowledge of forms and the classification of mental diseases became more exact and thorough.

From the present-time point of view, it seems strange that, with all the philanthropic efforts directed toward the insane and the renewed interest created in the study of the morphology of mental diseases, the influence of somatic conditions should have been so almost completely ignored. The psychiatrist of that day seemed to have forgotten that, as Cowles remarks, "In the study of mental diseases it is important to find their true place in relation to other pathologic conditions," and that "as a physician he must treat the whole body," for "psychiatry belongs to general medicine, and mental disease, like bodily disease, is not an entity nor an agency, but the result of normal function acting under abnormal conditions," etc.

It was not, however, until the diseases of women had been separated from medicine as a specialty that interest in their possible relationship to insanity began to be manifested. And it must here be remarked that the inception of this interest did not arise with the alienist who, busied with his large material, was seeking for the cause and origin of mental disorder, but with the gynecologist who noted the effect on the nervous system and mind of puberty, the menopause, and childbirth in certain individuals and observed the mental breakdowns resulting from ill-conducted lives, to which was added the continued irritation of abdomino-pelvic disease. He it was who drew attention to the possibilities of cause and effect in this class of cases.

In 1854, fired by an enthusiasm begot of experience with pelvic disease in the sane, Dr. Horatio B. Storer sought to carry his investigations forward in instances of unbalanced mind, and in a resolution offered before the American Medical Association, effected the appointment of a special committee to look into the relationship between insanity and the disorders peculiar to women. Unfortunately for all concerned, this proposal met with cold reception from those whom it would be supposed would be mostly directly interested; asylum superintendents became at once jealous of their so-called rights and the invasion of the gynecologist into the realm of psychiatry and refused to cooperate, so that, after an existence of several years, the committee was finally discharged, having accomplished nothing. A number of years then elapsed before a second attempt was made to study this important subject.

Somewhere about 1878, at the request of the superintendent, Dr. A. J. C. Skene undertook some gynecologic work in the Kings County Asylum at Flatbush, N. Y. The work accomplished was of the highest order, and it is to be regretted that it could not have been longer continued until more definite results had accrued from the observations made and our knowledge along this line thus augmented.

More than twenty years ago, when I began my work at the Eastern Michigan Asylum, no systematic efforts were being made to ameliorate the condition of female patients in our institutions for the insane suffering from abdomino-pelvic disease, or to place on a sound basis the knowledge of the influence which such disorders might exert on the causation and progress of mental troubles. Advancement in general medicine had by this time paved the way to a more enlightened order of things so that, although there was still opposition and criticism, the path was made easier and the way was more direct.

To-day, as the result of these tentative beginnings, there is hardly an asylum of size in this country where either a consulting gynecologist or a member of the staff, set apart for this duty, may not be found.

And there is one particular reason for this, a reason which I have persistently urged, and to which both laity and the profession have now become alive. If the state obligates itself to the care of the insane in the way of feeding, clothing, protecting and housing, it can not do these things and refuse its unfortunate charges relief from physical suffering; it is morally bound to care for bodily ailments while seeking the alleviation of mental distress.

But the question may be asked: If amelioration of bodily suffering has become a part of the asylum's function, what has been achieved thereby as regards the mental condition of the patient, and what are the end-results in the matter of mental cure? The answer may be found in the reports of asylums where this work is most actively carried on, and in the literature of insanity relating to this subject.

Summarized, we may recount a few of the conspicuous results that have obtained during the past two decades. We have added to our knowledge regarding the relationship existing between mind and body; we know more at present than was formerly known, that, while mind may exert a remarkable influence over the functions of the various internal organs, the converse is also true, morbid state of any viscus often aggravating the existing mental malady, or even lead to the ultimate downfall of the greatest intellect. Head, in his Goulstonian Lectures for 1901, has shown that physical pain from visceral disease is productive of decided psychic manifestations, and I and others have demonstrated that relief from suffering brings about a mental [illegible]tion often otherwise unattainable.

The frequency with which abdomino-pelvic disorders exist in insane women has been determined and has led to a more careful and systematic examination of the female patients in our institutions for those conditions which the mental malady may overshadow in its manifestations. My own investigations have shown that about 81 per cent. of insane women suffer from some form of pelvic or abdominal disorder[illegible] these statistics do not differ materially f[illegible] of most other observers, Hobbs and Isabella [illegible] alone reporting so large a percentage as 93.

The frequency with which post-operative insanity of a more or less permanent form is likely to occur following surgical intervention in, particularly, diseased abdominal and pelvic viscera, and the relationship and frequency of abnormal mentation to pregnancy, eclampsia and the puerperium has been shown. Postoperative insanity is of rare occurrence and satisfactory statistics can be obtained only from asylum records. From a careful investigation Dewey concludes that the ratio of cases of mental alienation from this cause going to public institutions is less than 1 per 1,000, and my own observations quite accord with this. Such statistics, however, are misleading and do not represent the actual number of cases of insanity resulting from surgical operations, since many instances are undoubtedly of an ephemeral nature, lasting but a few days or weeks, and, being cared for at home or in a general hospital, are not made public. Bearing on this point, the investigations of Sears published some years ago are of interest. The preponderance of mental disorders following operations appears to lie with women, since mental breakdown is more likely to result from operations on the pelvic organs than on other parts of the body, the eye alone excepted. Excluding the surgery of the sexual organs, women do not appear to be more liable to insanity than do men. Dewey and others direct attention to the fact that the mental condition of the patient prior to operation is not sufficiently taken into consideration, and that in many instances insanity is either actually present or the patient it at the border line before the surgical procedure is undertaken. As regards insanity following eclampsia, my investigations published in 1895 indicate that, for this country at least, it is probably such an infrequent sequel that eclampsia hardly deserves consideration as an etiologic factor. Of 1,271 insane patients, the puerperal condition, aside from eclampsia, was ascribed as the existing cause of the mental disorder in 108 instances. According to Kraepelin, childbed is responsible for the insanity of 6.8 per cent. of all women admitted to our institutions, while Peterson says that in about 10 per cent. of insane women the mental disturbance has its origin at the epoch of reproduction. In this connection Hobbs has pointed out that in the majority of these mental states septic infection, immediate or remote, is the responsible agent.

It has been more clearly shown that the hallucinations and delusions of the insane are not always the figment of a disordered brain but are frequently dependent on intra-abdominal or pelvic lesions. In 1896 I pointed out, in a series of illustrative cases, that these mental phenomena are often the expression of somatic peripheral irritation. Hallucinations from such causes may [illegible]velop in the sane, as witness a case reported by [illegible] which the removal of two apparently [illegible]ls relieved the patient of a fancied foul breath. This was undetectable by others, but, in spite of absolutely healthy organs and a normal mentality, was the cause of much mental distress to the patient. Head found that hallucinations of vision, hearing and smell may appear in phthisis, heart disease and aortic aneurism. My observations go to show that delusions may develop from external or visible bodily conditions, from easily detected visceral disorders, and from obscure abdominal and pelvic states. The delusions of micromania may often have foundation in some such perversion of [illegible] sensory impression, the erroneous judgment exc[illegible]eral adhesion, a tumor or ovarian irritation, may give rise to the impression that the intestines have been removed or are absolutely closed up, as in a case cited by Frederick Peterson. "It is further demonstrated," says Stoddart, "that all these mental symptoms arise in association with severe prolonged pain resulting from disease of the viscera referred to the body wall," and again, "they do not occur in the absence of pain." Further investigation may show that still more of these manifestations are really based on physical causes.

Finally, as to the end-results and the curability of insanity through operative measures: It has always been a popular notion, fostered no doubt by indiscreet and thoughtless observations on the part of the profession, that insanity in women is most frequently the direct result of a diseased condition or perverted function of the organs of generation, and hence, it has been believed, that the restoration of these parts to a normal state, either by repair of defects or the removal of pathologic structures, would lead to renewed mental health. To those who have had the largest opportunity to study these questions, however, experience has shown that this is not altogether true. While, as has been pointed out, abdominal and pelvic disease is found to be present in a large percentage of insane women, it is possible that the proportion is no larger than obtains among the sane. The latter, however, may be for years the subjects of great suffering, discomfort or distress without the local disorder producing the slightest effect on the action of the mental machinery. It is too generally forgotten by those who make extraordinary claims as to the curability of insanity through the removal of the particular local flaw, that in the insane the mental malady has, in the majority of instances, an unstable nervous organization as its substructure. It has been put down that the proportion is about 1 to 300, this varying with races and countries (Peterson). In the mentally diseased the frequency rôle of heredity, including "hereditary equivalents," is variously estimated at from 30 to 90 per cent., and even in the functional psychoses it may amount to as high as 70 per cent. (Krauss).

If we also take cognizance of the disastrous effects of alcoholism, syphilis, tuberculosis and the strenuosities of modern life, we have an alarming array of etiologic influences constantly threatening mental integrity. In the unstable individual slight causes may, perhaps, be quite sufficient to overcome the mental equilibrium, but in those with a clean record something more than the abdominal or pelvic disease must account for the psychic overthrow. After persistent and patient investigation of cases in private, hospital and asylum practice, and the study of the reports of others, I am still unconvinced that local disorders, exclusive of septic or toxic conditions, ever result *per se* in mental dethronement. Given an ordinarily strong and healthy woman and subject her to unusual and prolonged mental strain, anxiety and loss of sleep, together with bodily over-fatigue and stress, or to excesses which undermine the general health and constitution, and a dormant defect, which previously produced no symptoms, may make itself manifest and mental breakdown result from the combination of processes. Hence the uterine, ovarian or other disease, through its newly acquired power of pain and its influence on the nutrition and functions of the body, becomes an important factor in producing mental depression, which, in turn, may ultimately lead to insanity. Of itself the pelvic or other morbidity is but a phase and would have no effect had not the preceding physical and psychic conditions rendered the patient incapable of resisting its action. Such cases are particularly amenable to relief and cure through proper moral and physical treatment, supplemented by the surgical removal or correction of the local lesion. This also applies to many instances of puerperal insanity the result of infection, inflammation or physical prostration from undue demands made upon the organism unequal to the strain.

Again: "It is not unusual to find," says Mabon, "that insane patients, while convalescing from surgical operations, at times give evidence of mental improvement, going on, in some instances, to complete recovery, and this in instances in which the latter could hardly be expected. Sometimes this outcome may be due to the shock of the operation; in other cases the mental effect which the operation itself produces in the subject is to be credited with the mental improvement—the explanation being that we substitute a healthy for an unhealthy mental introspection; while in still others the increased personal attention received after the operation, together with the changed environment, forms the medium through which mental improvement results."

But though we are sure of a small percentage of mental cures following surgical operations on the insane, I still continue to maintain that we have no right, either as surgeons or humanitarians, to place the positive relief from physical suffering alongside the uncertain relief of the mental malady, but that whatever may be the outcome as regards the psychic disorder, relief and cure of somatic suffering is imperative, and this should be our constant thought and purpose.

But whether a cure of the insanity is effected or not, it is certain that improvement in the metal condition is *likely to supervene from the removal of the focus of irritation*; the subject is rendered more comfortable and therefore becomes more tractable, and through this is often changed from an untidy, refractory patient to a clean, industrious and orderly individual.

In the foregoing remarks I have attempted to touch on some of the conspicuous results that have followed from the investigation of insanity in its relation to the abdomino-pelvic disorders in women during the past twenty years. In the discussion I have credited the alienist's present point of view rather than that of the gynecologist, lest I be accused of bias; and whatever has been quoted has been set down largely in the psychiatrist's own words. If the gynecologist was once thought to be unwisely urgent and filled with over-zeal, the results of his good and persistent endeavors have won their reward and are today reflected in the changed attitude of students of mental disease. And surely such a showing can not be disregarded or attributed to over-enthusiasm on the part of those engaged in the work, for it can hardly be asserted that the alienist and the surgeon, together striving toward one end in harmonious effort, can both be deceived in so carefully wrought out and important a matter.

THE CHOICE OF OPERATIONS FOR RETRODISPLACEMENTS OF THE UTERUS [*]

A. E. BENJAMIN, M.D.
MINNEAPOLIS

In presenting this subject for consideration, I am not unmindful of the fact that much has been written and said on it, and that many of the members of this Section have worked out operations of their own to correct a retrodisplacement of the uterus. Where there is such a diversity of opinion, one must conclude that no one operation gives universal satisfaction and that the factors entering into the cause of retrodisplacements are not generally understood.

It is with the hope of bringing out a thorough discussion of this subject that I present this paper. This question will be settled aright in time as other surgical questions have been in the past, and the proper operations selected.

In the first place we must acknowledge—although many physicians of Europe and America dispute these points—that a woman who has a simple retrodisplacement of the uterus may suffer because of the displacement, and that a retrodisplacement predisposes the patient to disease of the uterus or adnexa. When a displacement is associated with disease of the tubes or ovaries nearly all agree that something should be done to rectify the trouble.

POSITION OF THE UTERUS

The uterus is partly suspended and partly held in position by ligaments. Why its normal position is maintained is not universally understood.

The uterus that causes no discomfort to the patient is usually anteverted, slightly flexed, and placed at right angles to the vagina. The fundus is supported by a soft cushion, the bladder, and held forward by the restraining round ligaments and their peritoneal coverings, also by the uterosacral ligaments, which prevent prolapse. The broad ligaments prevent permanent lateral displacements. The intra-abdominal pressure and intestines assist in holding the fundus forward and the counter-pressure of the perineal body makes the normal position possible.

The position varies with the condition of the bladder and rectum. The organ is freely movable and its position can be temporarily changed by manipulation. It moves with each respiratory act. With the broad ligaments it divides the pelvis into two unequal portions, viz., a shallow anterior part containing the bladder and a deep posterior portion containing coils of intestines.

CAUSES OF RETRODISPLACEMENTS

In the normal state all the supports of the uterus act in harmony during local or general muscular exercise. In diseases this synchronous action is disturbed. In many individuals a retrodisplacement is coincident with a general disturbance of the equilibrium of the abdominal and pelvic organs, and under such circumstances it increases the possibility of a visceroptosis. A general visceroptosis, on the other hand, aggravates the displacement.

The factors which disturb the harmonious action and arrangement of the uterine supports may be enumerated as follows:

1. A laceration of the cervix or disease resulting therefrom.
2. An endometritis or metritis.
3. Increased weight of the uterus.
4. Cervical constriction, resulting in congestion.
5. Tumors of the uterus.
6. Senile or small uterus.
7. Diseased tubes.
8. Diseased ovaries.
9. Congenital weakness of supports.
10. Lacerated perineum.
11. Inflammatory diseases of the pelvic organs or peritoneum.
12. Increased intra-abdominal tension.
13. Relaxed abdominal muscles.
14. Prolapsed intestines or other viscera.
15. Constriction at the waist-line.
16. Constipation and straining.
17. Jars or traumatism, weakening the supports or disturbing the equilibrium.
18. Temporary and habitual partial displacements from bladder, overdistention, etc.
19. Overdistention of rectum and pressure upon the temporarily displaced fundus.
20. Adhesions pulling the uterus out of place.
21. Improper exercise, poor food and lack of hygienic surroundings.

When a uterus becomes temporarily retrodisplaced—and this condition occurs at short intervals—the supports weaken. The forces which in the normal state help to hold the uterus forward, viz., the intra-abdominal tension and pressure of the intestines, now are factors in perpetuating the displacement. The ligaments stretch more and the fundus is pushed into the deep posterior pit and a pronounced retroversion and flexion often occurs.

Could we but recognize the incipient stages of this progressing condition and know every factor entering into the trouble, much could be done to avoid a permanent displacement.

SYMPTOMS

Occasionally unmarried women especially do not know to what their symptoms are due until a physician makes a diagnosis of a retrodisplacement.

It is frequently the case that the displacement alone is not the cause of the trouble, but the associated disease of the tubes or ovaries. Many young women have retrodisplacements and develop disease of the tubes or ovaries later because of this displacement.

The symptoms are dependent on the degree of retrodisplacement, the character of the infection, if any, and the associated conditions, also the age and social status of the patient.

That simple retrodisplacements do cause trouble I am quite certain, or at least I will state that in many instances in which the retrodisplacement alone has been corrected the symptoms have disappeared. Symptoms are modified by any condition which may disturb the harmonious relationship of the organs or assist in producing the retrodisplacement, as enumerated above.

In a retrodisplacement some of the special complaints which women make are:

1. Backache.
2. Bearing-down pains.
3. Tenderness of uterus.
4. Constipation.
5. Dysuria.
6. Dysmenorrhea.
7. Menorrhagia.
8. Metrorrhagia.
9. Neurasthenia.
10. Sterility.
11. Leucorrhea.

---

[*] Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

If cases of anteflexion do cause trouble at times, why should not a retrodisplacement in which there is the possibility of the uterus falling so much lower in comparison? The uterus being below the normal circulatory level, the venous return flow is impeded. Congestion, endometritis and metritis follow as natural consequences.

In any disease of the ovaries, tubes, or in appendicitis with peritonitis a retrodisplaced uterus greatly augments the suffering. The fundus and adnexa become congested and are crowded as a mass into the bottom or apex of the pit, pressing on and adhering to one another. A loop of the intestines is often intimately associated with this mass. The destruction of tissue is then greater and functions of the organs are much interfered with.

Many an old woman will give a history of displacement of the uterus from which she had suffered from girlhood. It had troubled her at menstruation, at defecation and at micturition, the peace of mind and body being so disturbed as to make life unbearable, and the condition ended in greater disturbances of bladder and bowel, with complete uterine prolapse. It had been the bane of the woman's life and did not even disappear at the "change of life," as often predicted, but followed her during her declining years. Countless office treatments have been given and numerous instruments of torture have been employed to overcome troublesome retrodisplacements, with little benefit, and often much harm, so there is a crying need for a sure and certain cure by a safe and sane method.

OPERATIVE TREATMENT OF RETRODISPLACEMENTS

In considering the surgical treatment for retrodisplacements it is necessary to understand all the factors entering into the maintenance of the normal position, and also to recognize what one or more conditions present may have a causative relation to the misplaced organ.

The success of an operation for the replacement of the uterus will depend largely on the interpretation of these factors and the attention given them by the individual operator. No operation will prove its real worth or give the desired relief should a general relaxed condition of the abdominal muscles with visceroptosis or a lacerated perineum go unheeded, or if any other pelvic or abdominal lesion exerting any influence on the position of the uterus remain untreated.

All sorts of operations have been performed in the past for the cure of retrodisplacements, many without regard for the future comforts of the patient or for the proper functions of the pelvic organs. The greater proportion of them looked all right at the time of the operation, but statistics and facts have shown that many have been failures. A few have stood the test of time, but only when properly selected and employed, with due reference to all other associated conditions.

The operation of ventrofixation and suspension, as introduced in the United States by Howard Kelly, was once quite popular and is to-day performed by a number of operators. It is true of this operation, as well as of any other, that when performed improperly and by incompetent men bad results are often to be expected. This operation has given a great many women comfort and ease. On the other hand, it has resulted in much harm and unnecessary suffering for others.

When properly performed on women past the menopause in whom there is a call for a rapid operation and for the suspension of the organ for retrodisplacement and prolapse, the results will be quite satisfactory. Also, in women who have the tubes or ovaries removed, and if a septic condition exists, at the time, there is less danger of complications in simply stitching the uterus to the peritoneum. Other excuses for its employment might exist in small, round ligaments, or in cases in which the uterus is to be held forward temporarily after an operation for appendicitis, fibroid, salpingectomy, or cysts of ovaries.

I myself have seldom selected this operation, because of the fact that there are more desirable methods of holding the uterus up. By this procedure the uterus is held in a fixed unnatural position and by an unnatural ligament. It seems like a makeshift operation. It is at variance with the principles governing the normal position of the uterus. It causes disturbances during pregnancy and makes labor difficult at times. It favors adhesions of the bowels and invites obstruction by the central ligamentous band.

Alexander's operation is not a very popular one today because of the fact that failures have been numerous and the operation has been improperly applied or performed. The round ligaments, especially the proximal half, are sufficiently strong to act as good supports when there is not a constant strain placed on them.

Any operation which manufactures or secures good supports for the uterus will not be ultimately successful if there is a constant strain on these supports. Failure will result as the tissues will stretch; therefore it is necessary to bring about the normal relationship of the uterus and surrounding parts, utilizing all the normal supports for the purpose and distributing the intra-abdominal pressure in a way to favor the maintenance of that normal position, at the same time correcting any associated disease acting as a causative factor. At one time this operation promised to be the panacea for women with retrodisplacements. There is no question as regards its efficacy in certain cases and it is a scientific and logical operation to perform in cases in which no disease exists within the abdomen or pelvis that requires a laparotomy.

In the past the enthusiastic advocates of this operation employed it in all cases, even going so far as to open up back of the uterus to separate adhesions due to diseased tubes and ovaries, packing the space and shortening the round ligaments extraperitoneally. The absolute failure to relieve the symptoms in all such cases and in many others caused the operation to fall into disuse. I have in a number of instances enlarged the opening to remove a diseased appendix or to resect a tube or ovary where no adhesions existed with good results. I believe it is best to draw the peritoneum up through the opening and close off the sac from the peritoneal cavity, as it makes a better support to include the peritoneum, especially the anterior fold.

The Webster operation finds a great many advocates. I have employed it in selected cases. It has the same objections as any other operation which does not permit the use of the strongest portion of the ligamentous tissue. It also produces a considerable constriction of the body of the uterus by the back-folding, clamping method of the ligaments. I am not sure but that much interference with pregnancy will be found to follow this operation in the future. It also introduces an extra suture line for possible complications. It is of advantage where a sustaining force is required for the ovaries and tubes, and, especially in cases where a raw surface posterior to the uterus exists, it protects this surface from possible adhesions.

Dr Coffey[1] of Portland, Ore., in a well illustrated article published October, 1908, describes an operation of his own for retrodisplacements. It consists in folding the round ligaments downward in front of and lateral to the fundus and refolding them up to the horn of the uterus, making a tuck in the broad ligament over these folds. He claims perfect results. It is a rational operation in certain cases.

The additional time consumed in the operation and the fact that the weakest portion of the round ligaments remain as the supports, the largest and strongest portions being used up, the additional amount of traumatism and suture line left within the tissues and abdomen, would naturally favor adhesions between these areas and the bowel. In septic cases there may be an additional risk of infection and general adhesions. Theoretically it would interfere with the natural enlargement of the uterus during pregnancy also, as there remain two folds of the ligament and one of the peritoneum to prevent the natural enlargement; pain or miscarriages might possibly result.

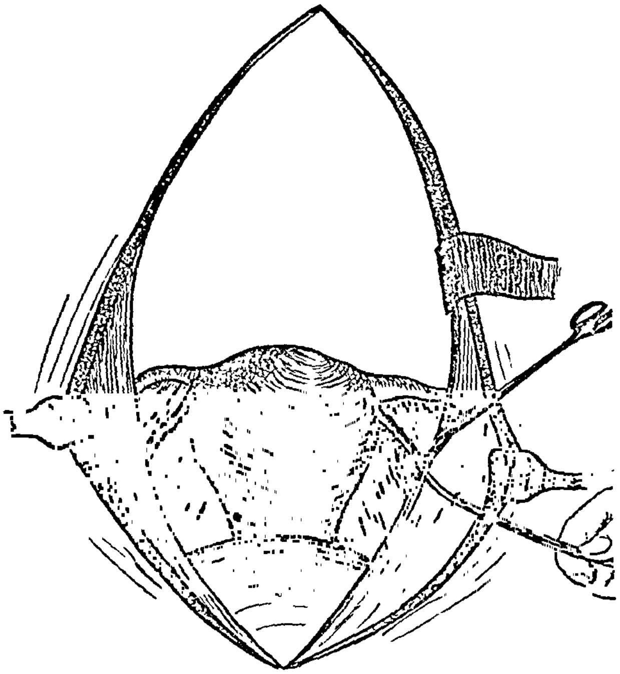

Fig. 1.—First step of modified Gilliam operation; forceps dragging round ligament through fascia opposite internal abdominal ring.

There are certain well-defined cases of lengthening of the uterosacral ligaments, as when there is some prolapse of the uterus, in which a shortening of these structures favors a more speedy return to health and lessens the possibility of prolapse.

The ligaments can be shortened from above or below; I believe best from above, as we can explore the abdomen and pelvic contents at the same time.

These ligaments should be shortened in certain cases where any other operation is performed for a retrodisplacement to insure good results if they are weak.

Any operation which folds the round ligaments on themselves within the pelvis, as in the Mann operation, does not offer the same support for the uterus, as it may be very heavy and partly deformed, flexed or bent on itself. Relapses may be frequent; the weak end of the ligaments are not strengthened; in fact, the additional constant restrain put on them by shortening may weaken the external thin ends.

I would offer the additional criticism on the Mann operation that there is, as in similar operations, the exposure of a suture line within the abdomen which may provoke adhesions. The same objections could be offered to the Goffe operation.

The operation of fixing the round ligaments and covering to the parietal peritoneum near the internal abdominal ring is a much more successful operation than many, as it allows a broad approximation and, if the loose distal portion of the ligament is tacked up to the abdominal wall there is an elevation of the pelvic peritoneum as well. It is not employed as often as it should be. I have been pleased with it in special cases. I believe it is far superior to the operations which leave the weak external end for support or in which an extra and unnatural ligament is created. The operation can be done through the median incision and quickly, but furnishes a chance for adhesions along the suture line. The operation of vaginal fixation as employed by Müller has not appealed to me, as it makes too radical a change in the position of the uterus and in young individuals would certainly not be indicated.

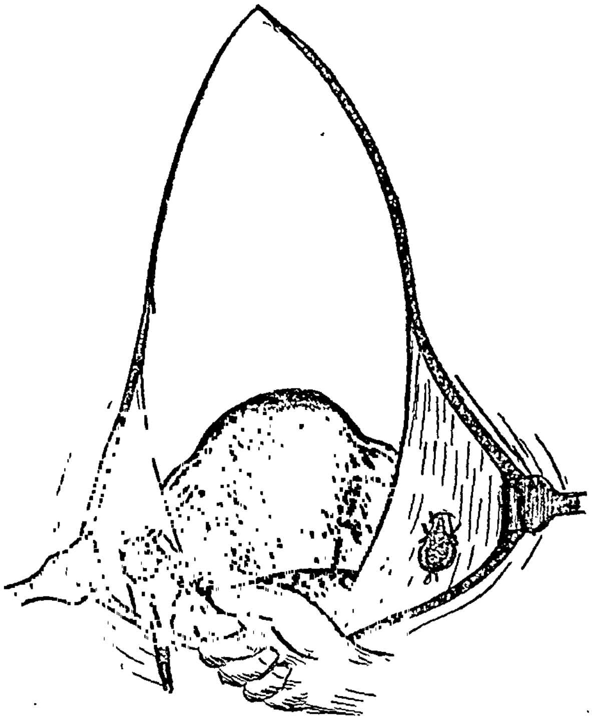

Fig. 2.—Second step of modified Gilliam operation; sutures being placed and ligaments fastened fan-shaped on opposite sides to fascia of external oblique.

Ferguson was one of the first operators (1899) to recognize the importance of correcting the disease of the adnexa and explore the abdomen for other lesions before correcting the retrodisplacement of the uterus. His operation was a step in the right direction, but has been replaced by the Gilliam operation or its modifications to-day. The typical Gilliam operation as first planned by its originator made too direct a pull on the uterus and left an unguarded depression between the normal and artificial exit of the ligaments inviting intestinal obstruction.

The modification which I have at last worked out consists in a dissection of the skin back to a point opposite the internal abdominal ring, passing a curved forceps through the fascia at this point between the folds of the broad ligament to within an inch and a half of the horn of the uterus, catching the ligament, which, together with the peritoneal covering, is brought out on the abdominal wall (Fig. 1), spread on the fascia in fan shape and anchored by three or four interrupted chromic catgut sutures (Fig. 2).

---

[1] Coffey, R. C.: Principles on Which the Success of Surgical Treatment of Retrodisplacements of the Uterus Depends, Surg. Gynec. and Obst., October, 1908.

The anterior fold of the peritoneum can be pulled out to any extent, making any tension desired. In young women I am in the habit of making a transverse curved skin incision at the border of the pubic hair line and a longitudinal incision through the underlying tissue.

I am always careful to observe the condition of all the organs within the abdomen and pelvis and to correct any abnormal condition possible at the time. A lacerated cervix, or perineum or cystocele must necessarily be overcome if present, usually after the abdominal work.

The after-care of these cases is important. The general visceroptosis may be corrected by a proper long straight-front corset; the intra-abdominal tension by correcting the diet and regulating the bowels, treating a menorrhagia or metrorrhagia by rest and medication; and the inflamed or congested cervix by hot and astringent douches.

When all the associated or interdependent diseases and symptoms are thus carefully managed the results are all that could be desired.

CONCLUSIONS

1. Retrodisplacements of the uterus often cause much discomfort.
2. The anatomic arrangement of the pelvic tissue invites a retrodisplacement which causes more discomfort than other forms of displacement.
3. The round ligaments and their coverings act as restraining bands, lessening the possibility of permanent retrodisplacement.
4. The harmonious action of all the supports is essential to the uterus for its normal position.
5. When the round ligaments become elongated by frequent repeated retrodisplacements the intra-abdominal force is misapplied and the displacement becomes permanent.
6. The operation which interferes with the laws governing the normally placed uterus is not to be advocated.
7. The operation which produces unnecessary intra-abdominal traumatism should not be chosen in the ordinary case.
8. Operations which could possibly interfere with the enlargement of the uterus during labor should be used in selected cases only.
9. Operations which leave an additional suture line within the abdomen may cause subsequent trouble.
10. Operations which do not give as strong a support as possible consistent with the normal functions of the uterus may result in failure in some cases.
11. The operation which utilizes the normal ligaments with little or no traumatism is less troublesome and more scientific.

The advantages of the modified Gilliam operation as I perform it are the following:

1. It employs only normal tissue for support.
2. The direction of the pull for that support is in a natural line.
3. It eliminates the weak portion of the ligaments in Nature's plan for the normal position.
4. It does not interfere with normal pregnancy or the uterine functions.
5. No additional suture line is present within the abdomen.
6. No traumatism to the pelvic tissue is produced and consequently adhesions do not follow.
7. It puts the uterus at right angles to the vagina and it elevates and tightens the broad ligaments and lifts up the ovaries.
8. It does not interfere with bowel or bladder functions.
9. It takes the strain off the uterosacral ligaments and favors their return to normal tone.
10. The ligaments are tightened sufficiently to prevent the temporary retrodisplacement; consequently the intra-abdominal pressure is properly distributed.
11. It allows the operator to investigate thoroughly the pelvic and abdominal organs.
12. When the harmonious action of all the uterine supports is restored this operation gives positive and permanent results.

302 Pillsbury Building.

ABSTRACT OF DISCUSSION

Dr. C. W. Barrett, Chicago: The question of treatment of retrouterine displacement resolves itself, not so much into the treatment of retrodisplacement as into the treatment of *retrodisplacement of the uterus and its complications*. In 1881, Dr. Alexander gave us the operation of shortening the round ligament, laying great stress on the external shortening of the ligament. A few years later, Olshausen, Kelly and others gave us the abdominal operation, dealing with the pathology and doing ventrosuspension. Ever since that time we have been trying to devise an operation that would give the advantages of the one without the disadvantages of the other, and it is only within the last few years that we have had an operation that practically covers that question. In any operation for retrodisplacement there are certain definite points of advantage which the operation should give us, and it is better to deal with principles when we may rather than with technic. The advantages which any operation must have at the present are: First, safety. We are dealing with a condition that does not cause death, and the operation must be safe. Second, simplicity. The operation must be simple because we must combine it with much other operating. Third, it must allow inspection of conditions within the abdomen. Alexander laid great stress on the fact that his operation was an external one; but for an operation to stand the test of time there must be an opportunity for the most careful inspection and correction of conditions in the abdomen, and the best part of the normal ligaments must be employed to hold the uterus forward. We must also deal with the ligament in a way that will leave it correctly placed, not running transperitoneally, but leaving the abdomen at the proper place, the internal ring, if that is possible. All these operations which have these advantages will stand what Goldspohn calls the double test of pregnancy; that is, they will allow pregnancy to progress to delivery without interfering with the success of the operation.

Those operations dealing with the best part of round ligaments may be divided into two classes: Those which get the ligament within the abdomen where it is easy to find, where it does not take up time, and those which find the ligament outside the abdomen. The latter necessitate a tedious dissection, and it is always doubtful about finding the ligament. After six years' experience with what I call the intramural transplantation of the round ligaments—that is, getting the ligament within the abdomen, taking it out through the internal ring—I have found that it stands the double test of pregnancy, that it does not interfere in any way with the pregnancy and that the pregnancy does not interfere with the holding of the uterus. It has been performed in women who were pregnant, and in whom it was necessary to open the abdomen for an incarceration of the pregnant uterus. Such an operation carries the ligaments out of the abdomen at the right place, the internal ring, and uses the strongest part of the ligament for holding the uterus and makes an anatomically and physiologically perfect operation for holding the uterus forward and allows the surgeon to do anything else necessary within the abdomen at the same time.

Dr. J. Wesley Bovée, Washington: Dr. Barrett has given us the proper principles to be followed in the treatment of these displacements, but he has given one operation for all. I hold, and I am not alone in this contention, that there is no one operation that is applicable in all cases. The principles of the proper supports of the uterus have not been satisfactorily worked out to many of us, and certainly the operations for the relief of deformities or defects in these supports have not been satisfactory. Whatever is needed to be done will depend on the condition that is present. I think shortening the round ligament in many instances will be sufficient. But there are so many other conditions that have to be considered; for instance, the defective attachment of the ligaments to the lower pole of the uterus which hold the cervix near to the outlet of the vagina, accompanied with abnormally long uterosacral ligaments. When uterosacral ligaments are attached so high to the cervix that they do not have sufficient leverage to hold it in the hollow of the sacrum no operation on the round ligaments will be of any lasting benefit. In one case I did ventrofixation of the uterus. Eight months later this patient entered Dr. Fry's service in another hospital and Edebohls operated by raising the uterus, appendages and vagina by sutures. The uterus was still firmly attached to the abdominal wall and the cervix eight inches away from that was protruding through the vulva, showing that the fundus might be fastened to the abdominal wall and yet procidentia be present. We see so many cases of procidentia of the uterus in which none of these ligament operations will suffice. Then, again, attention is attracted to the necessity of support from below and looking out for defects in the anterior vaginal wall; so that this field, when details are considered, is an exceedingly large one. I do not think that in any paper or in any number of days of discussion we are very much closer to an absolute determination of what ought to be done, except to find out that no one thing does, and no two things will answer, and that any gynecologic surgeon who depends on one; two or three operations for the correction of retrodisplacement of the uterus will find out sooner or later that he will have to enlarge his list of procedures.

Dr. H. J. Boldt, New York City: I feel that Dr. Bovée has struck the keynote when he said that no one operation is a panacea for retrodisplacements. It must be remembered that the Alexander operation was devised for patients who had a retrodisplacement with the uterus freely movable and with no disease of the adnexa. It is not proposed to cure a patient with procidentia by shortening the ligaments, as devised by Alexander. When the uterus is freely movable and there is no adnexal disease, if the operation is properly done, invariably good results follow. But we must remember that, in that class of cases, the greater number of patients will get along without any operation, a mechanical support alone being sufficient. In that other and larger class of patients with complications, such as diseased adnexa or adhesions of the uterus to the pelvic floor, the method of procedure will differ with the individual experience of the operator. I believe that in women well past the childbearing period no operation will equal ventrofixation of the uterus. But it should never be done on any woman unless she is past the childbearing period. The Gilliam operation or the one suggested by Dr. Benjamin I believe will answer in women likely to bear children.

Dr. R. B. Hall, Cincinnati: I agree that there is no one operation that should be used exclusively for retrodisplacement of the uterus. I believe that many conditions exist in which the operation should be varied. It is exceedingly rare, even after the childbearing period, that ventrofixation of the uterus should be done at all. My objection to the operation is the great danger of intestinal incarceration and intestinal obstruction. If we could gather all the cases of intestinal obstruction that have occurred after ventrofixation there would be a large number on record. I appreciate how one dislikes to report cases of intestinal obstruction coming on six months or a year or two years or longer after fixation of the uterus. I contend that with the many operations from which we may select, we owe it to our patients and to ourselves to choose a method which will not carry with it the possibility of intestinal obstruction.

Dr. H. O. Marcy, Boston: In my studies of inguinal hernia I find deformity in the construction of the inguinal canal in almost all the instances in which there is weakening of the lateral ligaments. As a consequence, it has been said as a basic principle that we should restore, so far as possible, everything to its normal pattern. The whole secret of cure of inguinal hernia is the normal reconstruction of the parts. Many factors must come into the problem, and it would be easy to write a small volume on this interesting subject. In restoring the weaker portion of the ligaments as referred to and fixing it beneath the peritoneum, we are at the same time reconstructing the weakened inguinal canal. In my later experience I open the abdomen and have everything under inspection. I followed Alexander's operation for a considerable period and was suprised to find failures where I looked for success. I was with Dr. Alexander and saw him operate and had him operate in my hospital. Then I did the other operation of intrafolding or fixing the round ligament to the abdominal wall. When the uterus is freely movable, other things being normal, reconstructing the inguinal canal and replacing properly within it the round ligaments solves in a very large measure this most serious problem.

Dr. Reuben Peterson, Ann Arbor: No one expects to convince anybody by this discussion. Every operating surgeon has his own way of dealing with retrodisplacement of the uterus and, no matter how much time we may devote to this subject here, every man will go home and to-morrow perform the operation he thinks best. We have heard a good deal about the Alexander operation, and of how it is not an operation for the retrodisplacement when the uterus is adherent. It seems to me, however, that Dr. Marcy has hit the nail on the head when he says that we should reconstruct the inguinal canal. The only way in which we can do that is to perform the Alexander operation as modified by Edebohls—opening the inguinal canal and shortening the ligament within the canal. Then, if we find a hernia, as we often do, it can be cured and the ligament shortened at the same time.

I have tried the various operations suggested for retrodisplacement of the uterus. My experience with ventrosuspension has been very bad. I have had to perform Cesarean section twice for dystocia developing after this operation, hence I never perform the operation in the childbearing woman. I have tried the Webster-Baldy operation. I found that while it is good for a certain purpose—elevation of the ovary—there are so many relapses that I have discarded it. Some years ago I adapted the Alexander method in all cases of retrodisplacement with or without adhesions when the uterus needed to be brought forward and held there. I do it through one incision, a transverse or median incision, taking care of all the pelvic pathology and then opening up the inguinal canal, shortening the ligaments, attaching them to the fascia with chromicized catgut sutures, and finally repairing the hernia if that be necessary. I have found two or three hundred cases of this kind in which the operation has given satisfactory results. Now, there will always be relapses from every kind of an operation for retrodisplacement. As pointed out by Dr. Bovée, we find that if we stitch up the uterus to the abdominal wall in a certain class of cases the uterus itself will stretch out and the cervix will appear at the vulva. We will find that after certain other operations the fundus will fall backward, but these are the exceptional cases. There will be fewer relapses after shortening the round ligaments within the canals than after any other operation for displacement.

Dr. I. S. Stone, Washington, D. C.: It seems a little remarkable that cases like these should be mentioned here and no explanation be given as to why certain displacements of the uterus are not curable. Now, take Dr. Bovée's case by way of illustration. Given a uterus whose fundus is fixed to the abdominal wall and, of course, there must be associated trouble with it, if the cervix of that uterus appears at the vulva. It would have been just as well for Dr. Bovée to state, what he knows so well, that the complications around and preceding that condition which have existed for years are the real trouble back of the displacement of the uterus. The cervix appears at the vulva in these cases, not because of its own weight, for the fundus may be attached to the abdominal wall as Dr. Bovée has stated, yet the relaxed ligaments, including fascia and connective tissue, yield before the intra-abdominal pressure from above. As has been said in other years, the reason we do not cure these patients is because we do not understand the pathology, and in the second place, we do not know how to overcome it. I feel sure that in nearly all the cases, whether in a virgin, a married woman or a multipara, the condition is preceded by a descent of the abdominal viscera. If such is the case, why should shortening of the round ligament overcome the trouble? It ought not to do it. The descent has begun in the viscera, the elongation of the so-called sacro-uterine ligaments, and the posterior pelvic peritoneum with the connective tissue has preceded the descent of the uterus. The uterus can not come down until the peritoneum and the posterior supports give way. We ought to recognize that. A great many of us have been trying for years to overcome the second condition first, and we have been getting the cart before the horse. How to correct the descent ought to be the object of every gynecologist instead of inventing some new method by which we can push the uterus back or hold it up. Let us have some papers on how to support the viscera, how to train the young woman so that there will not be the serious consequences to childbirth which are shown very frequently in the form of displacements which we are discussing to-day.

I would like to show why some of the ligament operations are failures. One of the reasons, which ought to be widely mentioned, is paralysis of the nerves in the ligaments which we are trying to shorten. The Alexander operation has failed because the ligaments are seriously injured by the compressing sutures. Webster and Baldy use the best part of the ligament and crush its nerve and blood supply, and when the abdomen is opened for correction of later mischief, a slender string of connective tissue is found with no muscular tissue in sight. Obviously, the ligaments should be secured without strangulation, for injuries to muscular tissue never permit a perfect restoration of function.

DR. HENRY D. FRY, Washington, D. C.: There are many different ways of treating retrodisplacement of the uterus surgically. Many men are perfectly satisfied with the suspension operation; I have had no trouble with it. Pregnancies have progressed normally and there has been no trouble at labor. But sometimes there will be fixation in these cases even when done properly, as Dr. Stone on one occasion did in the gynecologic department of the Columbia Hospital, and I had to deliver the woman afterward by Cesarean section. About fifteen years ago I was trying to find the best method of treating these cases surgically, and my thoughts ran in the direction of the Alexander operation, and I then saw Dr. Boldt operate, but the trouble he encountered led me to discard the thought of that operation. After a long search on one side for the delicate ligament and failing to find it, he went to the other side, caught the opposite ligament, returned to the opposite side and then caught it. Another objection is that the Alexander operation does not cure the complications which accompany retrodisplacement and which are the principal causes of the suffering. One of the most frequent is the prolapse of the ovary. The ovaries are down, and if the uterus is raised, leaving the ovaries down, the patient is going to continue to suffer. I have given up suspension, not from any personal dislike or from any bad experience, but simply because the profession seemed to want to get away from it and I felt that there must be good reasons. I have seen a few cases reported of intestinal obstruction, but have never had this complication.

In looking around for another operation, I then tried the Gilliam method. The trouble with that is the suffering afterward. I find that the Pfannestiel incision—the transverse incision—is advisable in cases in which there is no pus. This incision allows the surgeon to get at the parts much more readily and the operation is much simplified.

I want to say something now in favor of the operation which is here condemned—the Webster-Baldy method. I think that it is *par excellence* the best operation for retrodisplacement; the great advantage being in the lifting up of the prolapsed ovary. The surgeon goes through the broad ligament under the utero-ovarian ligament, catches the round ligament and brings it back in a way that not only holds the uterus forward, but lifts the ovary up. Strangulation of the round ligament has been spoken of as an objection, but I think that is because the operation has been improperly done. If the whole thickness of the round ligament is fastened down it will be strangulated, and it will be a little cord in a few years, but if only half of the ligament is sewed down and the two ligaments used, there will not be atrophy, but a perfect result. In a case reported by Dr. Baldy in which he had done the operation some time before and later took out the uterus, he found that the ligaments had grown into the uterine tissue and could scarcely be seen, but a good firm ligament held the uterus in place.

DR. MARION CRAIG POTTER, Rochester, N. Y.: I think that as gynecologists we are not more successful in curing these displacements by treatments, because we do not get the cases early enough. Advice has always been against the examination of unmarried women, and as physicians we should re-educate the public in this matter. In young women who have severe dysmenorrhea, especially if it has existed since the first menstrual period, some obstruction exists. School physicians when reporting to parents adenoids, eyestrain and defective teeth, should also call attention to menstrual derangements. Dr. Howard Kelly advises the examination of young girls under an anesthetic, and, if indicated, operative procedures.

At this age response to remedial measures for straightening the flexed canal is much more satisfactory, whether by dilatation, Alexander operation or routine office treatment, and such measures not only cure the discomfort, but, by establishing proper drainage throughout the generative system, they prevent the establishment of a "vicious circle," which is sure to follow interference with proper drainage of the pelvic organs, viz., endocervicitis, cervitis, endometritis, metritis, bacteriologic infection from retained alkaline secretion and possibly diseases of the tubes and ovaries. As a result of this symptom-complex, we often have the most unfortunate condition that can befall a woman—sterility. From the standpoint of preventive treatment of sterility, if from no other, we should create a sentiment for early examination of girls suffering from dysmenorrhea.

DR. GEORGE ERETY SHOEMAKER, Philadelphia: I want to speak in favor of the study of the patient, with a reservation in mind that retroversion in itself is not necessarily a condition which requires anything so important as either an Alexander operation or an abdominal section. I think operating on young women who have nothing except a retrodisplaced uterus usually is a mistake. I have always wondered how the large number of Alexander operations could be collected, and in studying my patients I could find few who required simply the reposition of a uterus. If they needed operation at all they had in addition a salpingitis, a diseased ovary, a prolapsed uterus, or some complication which called for more than the Alexander operation. The effort to determine which is the best operation, it seems to me, should resolve itself into the question: What is the best way to keep the uterus forward while the parts are returning to their normal after correcting other pathology in the pelvis? That is often a complicated problem, requiring all the knowledge of mechanics a man can summon to his aid. There is a very limited field for the fixation which has been so much condemned, and only when childbearing is impossible. It is an operation which helps bear up the badly prolapsed uterus after the other things necessary have been done, and usually a good many other things are necessary. There is a field for all the intra-abdominal shortening principles. If operating in the presence of pus and it is necessary to remove extensive adhesions which by contraction pull the uterus over backward, the surgeon cannot tear up the anterior peritoneum and inguinal canal intra-abdominally without some danger of spreading infection. In the presence of such conditions one of the other methods must be used. Light suspension in front of the line joining the cornua, I have done for several years with no unfavorable result. The round ligaments may be attached to the uterus behind, or some modification of the Gilliam operation may be used. I want to emphasize the necessity of the study mechanically of each combination of conditions and to state that we should very rarely operate simply for retroversion.

Dr. A. E. Benjamin, Minneapolis: It was the purpose of my paper to bring out a discussion, because I think this subject should be settled. Gynecologists should be agreed concerning the best operation to be performed. If these patients could be seen early, as Dr. Porter stated, before there were many complications, much could be accomplished. We should know whether there was visceroptosis or a greatly dilated stomach pushing down all the abdominal and pelvic organs and necessarily causing retrodisplacement of the uterus. If we could teach young girls how to overcome this condition there would be little necessity for an operation, except for complications, as some disease of the tubes and ovaries. Many patients will develop prolapse of the ovaries because of this continuous crowding of the organs down in the pelvis. I agree with most of the speakers regarding the principles underlying this subject. I cannot agree with men who believe that ventrosuspension should be done, although I have done it myself; I no longer do it because of the possibility of obstruction of the bowel from the false ligament.

I do not agree with those who believe the Webster operation, or those operations which shorten the round ligament within the abdomen, are ideal. As has been said, they use up the best part of the ligament. There is constriction of the uterus and interference with the blood supply. The idea of my operation is to utilize the same principle involved in the Alexander operation. The skin is dissected back from the fascia and a forceps run down through the tissue in the region of the internal abdominal ring; the round ligament is caught, pulled out, spread out and fastened to the abdominal fascia. The uterus is firmly supported and there is no pain or other trouble following the operation. I find that in this operation I can do a transverse incision nicely, especially in young women, by making a cut at the upper border of the pubic hair line. I carefully examine every patient to see that there are no other conditions to consider than the retrodisplacement.

If the abdominal muscles are relaxed with prolapse of the abdominal organs, I have these patients take exercise, put them in the knee-chest position, put on a long straight front corset, and then I find that gradually the organs assume the normal position.

Forestry and Health in France.—According to *Science*, France derives from her state forests an annual income of approximately five million dollars, or $1.75 per acre. Eighteen per cent. of the entire area of the country, or 23,500,000 acres is forest land. Approximately six million acres are managed by the state, the annual cost of management being ninety-five cents an acre. The great achievement of France in forestry has been the establishment of protective forests where much destruction has been caused by floods. Toward the close of the eighteenth century about 2,500,000 acres comprised in the Department of the Landes were little more than shifting sand dunes and disease-breeding marshes. This section is now one of the richest, most productive and healthful in France. The change has been brought about by the intelligent cultivation of pine forests. Immense forests now cover the country, the sand dunes and marshes have long since disappeared, and the wood, charcoal, turpentine, resin and kindred industries have brought prosperity to the department, which was formerly the most barren and miasmatic in France. The climate is now mild and balmy, the great change being wrought by the forests. The thin layer of clay beneath the sandy surface, formerly impervious to water, has been so pierced by the roots of the pine that there is now thorough drainage to the spongy earth below. The manufacture of resin, tar, turpentine, pitch, pyroligneous acid and wood vinegar is conducted in about the same way as in Georgia and the Carolinas.

THE PRESENT STATUS OF IRRIGATION AND DRAINAGE IN OBSTETRIC AND GYNECOLOGIC OPERATIONS *

HORACE G. WETHERILL, M.D.
DENVER

Though there may never be complete unanimity of judgment and opinion regarding the details of the requirements for irrigation and drainage in gynecologic and obstetric operations, there is a growing disposition among us to simplify our practice in these particulars. This has come about through the gradual elimination of the sloppy flushing practice of a few years ago and the abandonment of things like huge glass drains and suction syringes.

A process of evolution by exclusion has simplified the approved practice of today, and in both obstetric and gynecologic operations better results have been obtained with the simpler methods.

The use of solutions of antiseptic drugs, particularly those of the poisonous varieties, is steadily losing favor. The practical antiseptic efficiency of such solutions for irrigation is questionable and the dangers incident to their use are known and recognized. Not only have serious poisonings occurred but deaths from poison have resulted from this practice, and the diffusion and distribution of a previously localized infection has not infrequently occurred. An example of these dangers is afforded by cases in which uterine perforations have accidentally been made during a curettement following abortion, and a solution of bichlorid of mercury has been thrown into the peritoneal cavity through the uterine rent. In this event chemical poisoning and the distribution of the infection both take place. I have knowledge of one such instance; many may be found in medical literature, but for obvious reasons most of such unfortunate occurrences have not been reported.

Irrigation is doubtless best employed for its mechanical effect in washing out of the body such loose debris as the cavity being treated may contain. To this end the force employed should be at the minimum for efficiency and the solution used the least irritating possible.

The elementary principles governing the best modern obstetric and gynecologic practice would seem to be about as follows: Never irrigate if it be possible to avoid it through gentle wiping or sponging. Avoid poisonous and irritating solutions, as they are both dangerous and disappointing. In the main, use irrigation for its mechanical effect in flushing out debris, and always at low pressure.

Summarizing the prevalent opinions of today as to drainage in obstetrics and gynecology one finds it contrasting strongly with opinions and practice of but a few years ago, and happily, also, in the direction of simplification. One now finds himself disposed to avoid the use of drainage wherever possible and believes it possible to do without it many times where it was formerly deemed an absolute necessity. So, too, our ideas of drainage methods have undergone a change for the better. Glass drains are now rarely used even in the abdomen, and by only a very few operators. Gauze, always an indifferent drain, is more often employed for packing and walling off infected areas, arresting oozing of blood which may otherwise be difficult to control and for guarding against fecal and urinary infiltration into the tissues, and leaks into the cavities of the body when the hollow viscera have been injured or sutured.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The majority of the best surgeons of today limit the use of intra-abdominal irrigation and drainage to few and to certain specific indications, chief of which are rupture or leakage from some hollow viscus or localized abscess which has poured into the abdominal cavity food, urine, pus or blood in considerable quantities.

In certain cases of ruptured ectopic pregnancy irrigation serves the double purpose of flushing out the clots and debris and supplying the body with much needed fluid for the heart and blood vessels to act on. Also, in certain cases of shock, a normal salt solution instilled into the peritoneal cavity may act well; but that is not the particular phase of the subject this paper is intended to consider.

It is now generally appreciated that some localized accumulations of pus, particularly those of long standing and of tubal origin, may be safely broken down and turned out through an abdominal incision without irrigation or drainage even though the adjacent surfaces be extensively soiled. Indeed the plan of coffer damming and wiping out with dry gauze is believed to give much better results in such cases than did the older practice of irrigation and intra-abdominal drainage. So, too, certain localized peritoneal infections originating in the appendix are better treated without irrigation and intra-abdominal drainage even though the appendix may have ruptured and the adjacent loops of intestine be injected and mottled with many patches of lymph. Often in such cases the peritoneum will take care of its end of the infection without a protest, though the wound in the abdominal wall may suffer a serious infection which, if unprovided for by a superficial drain down to the peritoneum, may cause great anxiety. The interesting pathologic problems of established immunity on one hand and attenuated virility on the other are important factors under such circumstances, but these also lead us far afield and into a consideration of deeper mysteries than we are prepared to undertake to explain.

Whenever intraperitoneal drainage is really necessary in gynecologic surgery it is certainly better to make it from the bottom of the wound and "down hill" if possible; that is, through the vaginal vault. This plan has so many evident advantages other than the predisposition to hernia which a deep drain through the abdominal wall favors that they need not be enumerated.

Intrauterine irrigations in gynecologic and obstetric surgery have been illogically practiced for more than a generation, and even now poisonous solutions are constantly employed by many physicians who are doing curettements after abortions or after delivery at term, notwithstanding the fact that most of the recent authorities have shown them to be ineffective for good and capable of doing great harm.

The routine employment of such intrauterine douches after uncomplicated normal labors is also advocated and practiced, though the weight of evidence is overwhelmingly against it. In Williams' "Obstetrics"[1] may be found this statement:

> It has been shown experimentally by Bumm that mercuric chlorid injections penetrate the tissues only to a very slight extent. He took the liver of an animal dead of anthrax, and after soaking it for thirty minutes in a 1 to 1,000 mercuric chlorid solution, placed it on a freezing microtome, and cut thick sections from it. After cutting off about 1 mm. he inoculated the next section into another animal which succumbed to anthrax, thus showing that the germicidal action of mercuric chlorid had been exerted only on the surface. If this be the case in the laboratory after the tissue has been immersed in the antiseptic solution, what effect can be expected on organisms embedded in the muscular wall of the uterus, from a transitory application to the surface of a few liters of a weak mercuric chlorid solution? Bumm likewise showed that the streptococci made their way through the uterus with great rapidity, traveling 2 cm. or more in the space of six hours. What has been said concerning mercuric chlorid applies equally well to the other disinfectants.

Notwithstanding the frequent reiteration of statements like that just quoted in almost all the recent standard text-books on obstetric and gynecologic subjects, many general practitioners and not a few gynecologic and obstetric surgeons persist in the use, or rather the abuse, of the poisonous intrauterine douche. Proof positive has been offered time after time of the fallacies and dangers of the poisonous antiseptic intrauterine douche and there is practical unanimity of opinion among teachers and writers that its effects can be nothing but bad, and yet it is employed constantly by many who should know how dangerous it is.

What is there about the practice of the obstetric art that makes the average man so impervious to incontrovertible proof? Our reluctance to accept the truth in regard to the contagiousness of puerperal fever for almost a half century after it had been logically proved is an indictment under the shadow of which we should long stand in deep humility and in atonement for which all our efforts should be exercised in a determination henceforth to keep our minds open to conviction.

Intrauterine drainage is, under some circumstances, a most important surgical detail, but, so far as I have been able to observe, it is rarely employed logically or with a proper regard for the mechanical principles involved in the attainment of the ends sought.

From a mechanical standpoint, a tampon is little more of a drain than a dam is an aqueduct in hydraulics. If the conditions inside the uterus are such as to demand drainage in the true sense in which the word should be used, a gauze tampon, or even a gauze wick, if that term be preferred, does not meet the indications. The capillary action of gauze is incapable of carrying off under any circumstances more than the thinnest fluids, and even those only for a short time, as the meshes of the gauze soon become filled and its capillarity is destroyed. The principles of true drainage require that the drain shall be open and free; that it shall be capable of conveying thick fluids, such as pus, blood, mucus or necrotic debris, and that it be capable also of being flushed and freed while *in situ*.

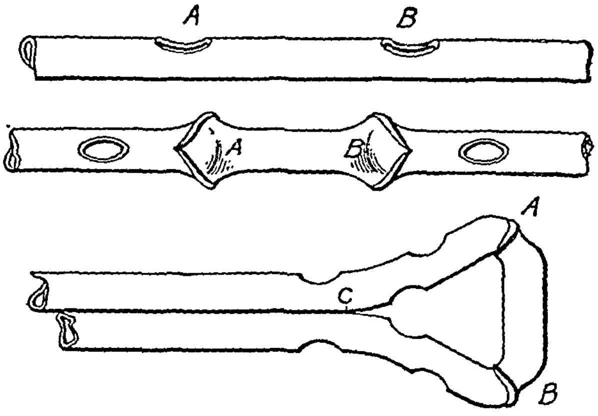
Such a drain is often invaluable in the uterine cavity, as it may be in many other situations; but, with the known tendency of the internal os to contract and so retain within the uterus putrescible or infected material, a free drain adapted to flushing and capable of conveying thick fluids is a necessity. Such a drain I devised some years ago and my experience with it has been such that I venture to speak of it here, notwithstanding previous mention of it elsewhere. It is made of rubber tubing of a size adapted to the requirements of the case in hand and of thick or thin walled tubing, depending on the pressure it must withstand from without. It may be adapted to bladder irrigation and drainage, as it makes an admirable and easily constructed retention catheter out of material always at hand and one that can be readily introduced and removed. It works equally well after operations for perineal or suprapubic prostatectomy and for draining the pleural cavity it is admirable, but as an intrauterine drain in infection, sapremia, etc., it has been found most useful. The accompanying drawing and legend will best describe its construction.

---

[1] Obstetrics, 1908, pages 885-886.

One of the most dangerous features of the ordinary intrauterine douche as it is commonly employed is the necessity for frequent and repeated introductions of the irrigator through the infected vagina and cervix with all the risks of a retrograde infection that necessarily attend such a proceeding. When practiced by the physician or nurse several times a day, as is sometimes done, it is inconceivable that the vaginal, cervical, or vulval bacteria are not conveyed into new fields during the operation and the patient may be congratulated if she does not also receive some new infection from the hands or instruments of the operator

Such retrograde infections of the bladder are of common occurrence as a result of the repeated use of the catheter, even though the opportunities for cleansing the field are good.



1. Cut two holes in a long piece of drainage tubing as indicated at A and B. 2. Draw one end of the tube through A and out at B, thus inverting that portion of the tube between the holes as seen in 2. 3. Bend the legs of the tube down so that the holes A and B will be left open for drainage. If bent in one direction they are open, if in the other closed. Tack with a blind stitch at C.

The advantages of an irrigating and draining device which may be placed once, and once only, with due precautions against infection and through which the drainage and the flushing fluid may always flow from within outward must be apparent, whether the cavity to be flushed and drained be that of the bladder, the uterus or the pleura. This flow from within outward is accomplished in a most satisfactory way by the tube shown. When used with diluted alcohol, according to the suggestion of Carosso,[2] or with sterile water, salt solution, a solution of potassium permanganate or a dilute iodin solution, it may be a means to a most desirable end.

Through these tubes an intermittent flushing of an infected uterine cavity may be made by a nurse at frequent intervals without changing the position of the patient in her bed, or, indeed, it may be done without waking her if she should be asleep, as one of the legs of the tube can be permanently connected with the reservoir containing the flushing fluid and the other with the receptacle beneath the bed, so that the fluid can be carried into and out of the uterine cavity by continuous flow, if that should become necessary, and be stopped or started at will with a simple pinch cock.

Dilute alcohol solutions (33 per cent.) so used have given astonishing results in the after-treatment of sapremia and uterine and vaginal infections.

With this simple device for drainage and a continuous flow of boric acid solution at low pressure success has also attended efforts to close large vesicovaginal fistulas in badly infected bladders, one person having been previously unsuccessfully operated on eleven times during twelve years. Success in this instance was made possible by the perfect draining of the bladder and the prevention or solution of the ammoniacal urinary concretions and incrustations which had been deposited on the catheter and bladder walls in her previous operations.

Drainage, real drainage, of the uterus and bladder under certain conditions may be indispensable.

When irrigation of these cavities is necessary it should be made with non-poisonous solutions, and in the main with a view to their mechanical effect in flushing the cavity as in contradistinction to their chemical and antiseptic effect.

Low hydrostatic pressure should be employed and ample provision must be made for the return flow of the flushing fluid.

ABSTRACT OF DISCUSSION

Dr. I. W. Potter, Buffalo: While douching following normal labor has its disadvantages and is said to be dangerous under certain circumstances, I think it also has its advantages, and with me it is a routine practice. I do it myself, but never dot it more than once in each patient.

Dr. W. W. Golden, Elkins, W. Va.: I wish to add my testimony from a somewhat extensive experience to the utility of the use of douches of solutions of iodin. This solution serves a useful purpose, especially under certain conditions in which the general practitioner often has to work, when it is not convenient or possible to exercise and practice proper aseptic precautions in intrauterine manipulations. The use of iodin solutions a little stronger than usually recommended has proved satisfactory in my hands and in the hands of a number of physicians who have followed my suggestions.

Dr. Edward J. Ill, Newark, N. J.: In considering the question of drainage of the uterus we must remember that the uterine cavity is not a hollow space, that the walls come together. No irrigation tube will separate these two surfaces sufficiently to keep the cavity perfectly clean. To do it well, the much-maligned gauze should fill the uterus. If the physician will separate those two uterine walls by gauze and through the center of it put a rubber tube up to the fundus with an opening at the end and pour a 25 per cent. solution of alcohol through it once in three hours, he can thoroughly cleanse the uterine cavity without in the slightest disturbing the patient. These septic surfaces are constantly bathed with a 25 per cent. solution of alcohol. Ahfeld describes scientifically the importance of disinfection with dilute alcohol. I have used this method for fifteen years and whenever I get hold of a patient within two or three days of the infection she recovers. If I get the case later than that, the infection has entered the lymphatics or the veins and the results are not so certain, though in many cases they are satisfactory. At the end of five or six days the gauze and tube are removed and the gauze is found to be just as clean as when it was put in. This gauze is not foul and ill-smelling and filled with all sorts of discharges from the uterine cavity.

Dr. Henry D. Fry, Washington, D. C.: I protest against what has been said about the use of intrauterine douches after normal labor. I am sorry that the doctor who said there were certain advantages to be derived from it did not state what they were, and I can not see what the benefits are. If the labor is normal and the uterine cavity is not *infected* there is danger of carrying infection into the uterus by douching it. This method has been tried and we know that the morbidity and mortality have both been increased by the use of the intrauterine douche when there is not distinct indication for its employment. I agree with the essayist that it seems to be very difficult to stop this practice among obstetricians; men who are supposed to be conversant with the best methods of treatment and that they will continue to use the curette also, which I think is dangerous, unless clearly indicated. I think there are distinct indications for it in some cases—infection, especially of the saprophytic kind, also septic endometritis, and when débris, foreign matter and clots have been retained. I think the effect is just as good from the use of normal salt or sterile water as from an antiseptic solution. It is the mechanical effect of the water that does good. If there is colon infection the douches are good. In streptococcus infection there is no advantage in the use of the douche. If streptococci are found, let the uterus alone after a preliminary cleansing.

---

[2] Wetherill: Am. Jour. Obst., 1903, xlvii, 5; Am. Med., Jan. 30, 1904, p. 189

One point not mentioned and which has given me much trouble is in connection with the vaginal operation for ectopic gestation with extraperitoneal hematocele; in which one opens through the vault of the vagina and through the sac, to get out broken-down tissues and clotted blood. I clean out and put in a double drainage tube, but I have not been able in a single case to prevent fever. I should like to hear the experience of some of the gentlemen in these cases. Notwithstanding my greatest care in washing out the sac and inserting a double drainage tube, I have had septic fever. All my patients have recovered, but I look for fever in such cases for about a week or ten days, and if anyone knows how to drain these cases and not have fever, I should like them to tell me.

DR. H. P. JACK, Canisteo, N. Y.: I do not believe the members of this Section, at least those with whom I have talked, know of the benefits to be derived by following Dr. Wetherill's technic. For the past five years in an extensive consultation practice I have seen many patients with septic infection of the uterus, some of the cases being of longer standing than mentioned by Dr. Ill, some of the patients almost moribund, and yet I have seen them recover under the persistent use of this technic. I commend the method; it should not be withheld in streptococcic infection. The alcohol is absorbed as well as the streptococci and how much good is done we cannot say. I have seen patients in whom the chills persisted, and multiple abscesses had formed at the points of pressure, recover under this treatment carried out for three or four weeks. I have never been able to obtain any such results with anything but alcohol, and I hope we shall have a more general use of a measure which is of such value.

DR. H. G. WETHERILL, Denver: Many of us feel that there is a very limited field for vaginal operation for ectopic pregnancy. While that field is limited, it has special indications which must be met, and one of them is "drainage," so-called, but in my judgment that is one of the forms of "drainage" to which gauze is better adapted than a tube. It approaches more nearly a need for a tampon than for a drain. My own practice, when vaginal operation is done for ectopic pregnancy, is to evacuate and pick out the clots as well as possible and to tampon with a wad of gauze. If in my opinion this will not meet the indications, abdominal section is done. The opinion of Dr. Ill I should have a great deal of respect for, because he has doubtless had a large experience with the intrauterine douche with alcohol solutions in sepsis and I have no doubt he obtains good results by his method, but in my judgment he is entirely in error in saying that there is no cavity inside the pregnant uterus. In the ordinary case in which pregnancy has advanced beyond six or eight weeks, the uterus is flabby and soft and its walls do not fall together as in the unimpregnated uterus, but whether there is a cavity or not is unimportant. Packing gauze into the uterus and leaving the gauze as a dam and not as a drain, interferes very much with the return flow from the uterus and it makes necessary—what is not necessary with the tube alone—the removal and changing of the gauze at short intervals. This is a menace to the patient because of the risk of retrograde infection.

A STUDY OF THE TRAUMATIC INSANITIES*

ARTHUR CONKLIN BRUSH, M.D.
Professor of Mental and Nervous Diseases in the Brooklyn Post-graduate Medical School; Neurologist to the Kings County, Brooklyn Eye and Ear, Williamsburg, and Bay Ridge Hospitals
BROOKLYN

The study of the question of the relationship of trauma to insanity clearly reveals the fact that medical opinions on this subject are not as yet well settled or defined.

Many writers, especially the older ones, hold that injuries to the head and cerebral concussion, by causing inflammation of the meninges which spread to the brain, disorder its circulation and nutrition and thus produce psychic disease, at once or after a long interval. This theory has not been sustained by the facts found in many cases, for the reason that the surgeon and pathologist have failed to show such a state of facts. If such lesions did exist they would have given recognizable symptoms (which actually have been entirely absent) during the interval. Most of the more recent writers have modified this view and hold that, with or without material injury, the shock produced by the accident may cause molecular changes in the brain, thereby producing psychic disturbances or a predisposition, especially in neurotic individuals; that such insanity may not occur until after a long interval, during which no special symptoms occur, and that the immediate cause of the condition is some later intervening factor.

This view is also open to objections. It must be admitted that, in those cases in which an interval of time occurs, these later etiologic factors are of themselves competent effective causes in persons who have received no such injury; that there is no proof of any such molecular changes if they produced no recognizable conditions, and that every human being has at various times in his life received injuries to the head of varying severity. Thus a history of head injury is of no more importance in an insane person than in other individuals. One of these authors is conflicting in his statements when he adds that the trauma must be of some consequence and produce cerebral concussion.

The solution of this question appears to be that both organic changes occurring after severe head injuries, and severe fright occurring with trivial injuries, may immediately or after a period be followed by psychic disturbances, and that in the latent cases the two must be connected by recognizable conditions.

One writer contents himself by stating that "all degrees of injury to the skull or brain may be followed sooner or later by progressive dementia." Such assertions as this are objectionable, as they form the basis for the assumption that any dementia occurring at any time after an injury may be due to it. The importance of this question from its medicolegal standpoint is very great, and the conflict of opinion has done much to discredit our profession as a scientific body.

Excluding hysteria, three psychoses seem to be well recognized as being the direct result of psychic or physical trauma, psychic trauma causing traumatic hypochondria, and physical trauma, acute primary traumatic insanity, organic dementia, or idiocy and imbecility.

Much of the confusion which surrounds even these psychoses is due to the fact that authors often attempt to describe them together as the result of head injury and thus fail to define the conditions clearly.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

TRAUMATIC HYPOCHONDRIA

The peculiar mental picture presented by many of the traumatic neurasthenias and hysterias caused them in the past to be described under the name of the traumatic neuroses and more recently under that of the traumatic psychoses.

The weight of medical opinion as to the nature of the condition in question, as shown in the more recent medical writings, is shown by the facts that Kraepelin, Oppenheim, Strümpell, Mendel and Bruns hold that it is a pure fright neurosis and differs from hysteria in origin, clinical expression and course; that Diefendorf states that the French writers, Schultz, Hoffman and Mendel, hold that it is either hysteria or neurasthenia; that Charcot held it to be purely a hypnotic condition; that Oppenheim states that the autopsy findings are usually negative, that a few cases have shown arteriosclerosis; that Friedman, Kronthal and Koppen consider it to be due to vasomotor disturbances; that Schmaus, Bickles, Vibert and Koppen believe that minute material alterations are concerned in the condition, and that it is in reality a combination of neurasthenia and hysteria with a peculiar mental state, and that Strümpell states that there is no material injury but purely a psychic change.

It appears from this statement that the hypotheses of some of the older writers of minute material alterations, a term which is exceedingly indefinite, has not been substantiated either by the course of the psychosis or the pathologic findings; that the presence of arteriosclerosis can not be regarded as of more than an accidental occurrence, for it has been found in only a few cases and is a common condition in mankind; that the fact that vasomotor disturbances should have been found in some cases is not of any importance, as these regularly occur in hysteria and hysteria regularly complicates this psychosis, and that the condition is a pure psychosis.

The condition may be defined as a fixed delusion on the part of the patient that he has sustained some severe and permanent injury as the result of some accident, and is often complicated by hysteria or neurasthenia or a combination of both. This delusion in no way differs from similar hypochondriac delusions due to other causes.

The producing causes for this symptom-complex are stated by Kraepelin and Diefendorf to be general but not severe injuries with but little shock, but accompanied by fainting and excitement; Kraepelin, Oppenheim, Diefendorf and Strümpell say that it is due to a tormenting anxiety and a morbid state of the mind and that it may occur without injury; Diefendorf says that it is a question if the emotional disturbances which occur at the time of the injury should be regarded as the cause, since frequently weeks or months elapse between the injury and the first symptom; Diefendorf and Strümpell state that an important factor is a claim for damages or a membership in an insurance society, and Oppenheim says that it may develop without a claim for damages. It appears, then, from this statement, that this condition may arise either from the happening of some accident or from the occurrence of other factors which may arise weeks or months after its happening.

A study of my cases reveals the fact that this delusion may arise from an exaggeration of the consequences of the injury, especially when founded on symptoms of a hysterical nature; from an error in diagnosis and prognosis on the part of the patient's regular medical attendant, as we not infrequently find hysteria diagnosed as multiple sclerosis, myelitis, cerebral or spinal hemorrhage, neuritis, concussion of the brain or cord, and epilepsy, from the fact that when legal proceedings have been begun the patient is apt to fall into the hands of a physician retained by his attorney, whose sole function appears to be to make the case appear as grave as possible; from the fact that the examination of the patient often discloses the existence of some previously existing condition of which the patient had little knowledge, which the patient attributes to his injury and becomes the foundation for his delusion, and from a claim of damages or membership in an accident insurance, which, although it may not be the direct originating cause, has an undoubted tendency to make the condition more marked. Usually we find more than one of these factors acting in the same case.

Of 31 cases, reports of which I have been able to collect and in which the condition is known after periods varying from seven to twelve years, 13 occurred in females and 18 in males. The ages varied from 21 to 58. Nine occurred in the third decade, 16 in the fourth, and 3 each in the fifth and sixth. It is then a psychosis of middle life—a period when the struggle for existence is most intense. This fact is emphasized by the social condition of my patients, as 29 of them belonged to the humbler ranks of life; their incomes were barely sufficient to meet their necessities, and anxiety about the nature and consequences of their injuries would be naturally most marked in such persons.

The character of the accidents were falls from the steps of cars in 8, falls from wagons in 4, blows on the head in 5, falls on the buttocks in 2, general commotion from collisions in 12—and 5 of the latter sustained no objective signs of injury. The physical results of these accidents were contusions on the head and body in 22, a Colles' fracture, a broken nose, a sprained back and a crushed hand in 1 each. These cases, then, support the contention that the physical injury is usually slight and that it is the fright and anxiety due to the accident which is the real producing cause. This fact is also shown by the immediate symptoms occurring in these cases, which were fainting in 6, daze in 7, shock in 3, and hysterical and real coma in 1 each. In the other cases there were no immediate symptoms. In all these cases a more or less marked condition of hysteroneurasthenia developed.

The psychosis itself developed immediately after the accident in 16 cases, while of the remaining cases a period of one week elapsed in 5, two weeks in 4, two months in 4, and seven months in 2. The influence of the character of the diagnosis and prognosis in developing the psychosis is very evident in my cases. In 7 of the immediate cases the condition was diagnosed as a serious and permanent injury, in 4 the character of the condition was recognized but permanency was claimed in 2, and in the remaining 7, in which a good prognosis was given, all made a quick recovery. In 4 cases the discovery of a floating kidney, a uterine displacement and an irregularity of the skull and ribs, which were claimed as fractures, was the foundation for the psychosis. The effect of the opinion of the physician who examined them on the part of their attorney is also evident, for in 9 a marked increase occurred in the symptoms after the examination, while in one personal case in which the patient was assured that his physician was mistaken in his having a spinal-cord hemorrhage, rapid improvement occurred. In 9 of the cases in which a period of time elapsed between the accident and the psychosis, the latter did not develop until litigation had been commenced and such examination made. In 2 of these an error in diagnosis on the part of the medical attendant had also been made.

As a result of such causes the patient's *mind* becomes dominated by a fixed delusion that he is suffering from a serious and permanent organic injury which has ruined his life. This delusion differs from the fear of evil consequences of the neurasthenic from the fact that the latter has some doubt of the reality of his fear, that he does not lose the hope of recovery, that his fears are not clearly systematized as in this condition, and that he never commits suicide. Loss of memory is often claimed, but is never real; the apparent loss, mental slowness and confusion, being due to the fixation of the mind on one train of the concepts. The patient becomes emotional, irritable, depressed, apathetic, avoids society, and is constantly talking about his miserable condition and his ruined life. In some cases there may be violent outbreaks, hallucinations, and suicidal attempts. With this condition we have as a rule hysteroneurasthenic symptoms.

The prognosis of this condition is of great medicolegal importance. Diefendorf holds that in light cases, even after a long duration, it is good, and that it is worse in cases with marked local symptoms; Kraepelin that many cases are obstinate in their course and that the condition often disappears after damages are paid, and Oppenheim believes that the prognosis is bad in cases with advanced arteriosclerosis, that marked cardiac or vascular symptoms make recovery rare, and that litigation and early return to work are unfavorable. In my cases 26 patients show, after a period of from five to ten years, a condition of complete recovery. Of the 5 patients who have not recovered, 3 are over fifty and show well-marked arterial degeneration and the other 2 have hysterical contractures. The effect on the prognosis of an early and correct diagnosis is well marked in my cases. Of the 26 cases in which recovery ensued, 14 were diagnosed as permanent organic conditions and 1 as a permanent form of hysteria; and in these cases recovery occurred in from one to five years; and in the remaining 11 cases in which a correct diagnosis and prognosis was made, recovery occurred in from two months to two years.

The effect of litigation in prolonging the psychosis is also clearly shown. In 21 claims for damages existed and in all but one no recovery occurred until such claims were disposed of. Ten of these cases came to trial. Six of the plaintiffs were given favorable verdicts and then recovered after periods varying from six weeks to four years. Of the 4 patients who were unsuccessful in their suits 2 recovered after periods of one year and 2 have not improved. In 10 of these cases settlement was made out of court, and 8 of the patients recovered after periods of from two to eight months.

ACUTE PRIMARY TRAUMATIC INSANITY

This form of insanity seems to be one for which an injury is the only recognized cause. It is also undisputed that trauma, to be the producing agent, must cause an injury to the brain, and that the symptoms of the insanity must be continuous with the symptoms of the injury or be connected with them by a definite train of cerebral symptoms.

That insanity is not a common result of head injury is shown by the facts collected by Meyer, who shows that in the Franco-German war only 13 cases occurred in 8,985 head injuries; that Stapler found 12 cases in 931, Meyer 1 per cent. in 3,000, Frost 1.87 per cent., Kiernan 2 per cent., Edel 2.5 per cent.; and I have found 1.8 per cent. in 1,668. The contention of Kraepelin, Peterson, Meyer, and Kellogg that the producing cause must be a severe head injury is supported by the histories of my cases, for they all show well-marked effects of cerebral contusion, as profound coma, and were complicated by fracture of the skull and meningeal hemorrhage in 6 each.

The assertion of Meyer that insanity occurring as the result of such injury is most often found in persons of a neuropathic heredity, or suffering from alcohol or syphilis, is supported by the facts found in my cases; an insane family history existed in 5, previous insanity in 4, alcoholism in 6, and syphilis in 8.

This form of insanity is one in which a definite lesion has been shown, both by the surgeon and pathologist; and that is the lesion of cerebral contusion. Fractures of the skull are not of themselves of any etiologic importance except as they show the severity of the producing cause or cause a compression or penetration of the brain. Such contusions are most common about the fourth ventricle or at the tips of the frontal or temporal lobes (Meyer). Microscopically they consist of minute lacerations, minute hemorrhages and thrombi, capillary stasis with cellular infiltration of the vascular walls and lymph spaces, and a localized or general edema. Meningeal hemorrhages of varying size are also common. It is well established that all these lesions except the large hemorrhages may entirely disappear; but in some cases the condition may be followed by permanent changes in the cerebral circulation and nutrition.

The clinical picture and course of a case of this form of insanity is held by Kraepelin and Meyer to be diagnostic of a severe cerebral contusion; and my cases fully sustain this contention, for in all the injury was followed by coma lasting from one to thirty-six hours, muscular relaxation, dilated unequal sluggish pupils, rapid feeble pulse, and followed by headache, vertigo, delirium and a rise in temperature. In the majority of the cases the insanity immediately follows the symptoms of the cerebral contusion, but in other cases a period of time intervened which was usually short, but, as shown by one of Meyer's cases, may be as long as twenty-three months. In my own cases the insanity immediately followed in 19, and in 9 a period of from six days to one year intervened. During this period these patients suffered from headache, vertigo, insomnia, irritability and change in disposition.

The invasion of the psychoses is rapid. The patients become excited and sleepless or somnolent, or the two conditions alternate. The mood varies from depression to elation, with no idea of illness. The patient at times is agitated and violent. Mental confusion is marked, as is loss of memory, especially for facts just before and following the injury. There is marked loss of knowledge of time, situation and identity of persons. The answers to questions are rapid, rambling, and the facts asserted are fictitious. Hallucinations and delusions, brief in duration and changing in character, are common. Objectively there is a general tremor increased by movement, indistinct speech, a spastic paralytic condition of the muscles with twitching, and occasionally convulsive attacks of the petit or grand mal type. The deep reflexes are increased and Romberg's sign with ataxia of the limbs is common. The pupils vary at different times and may be dilated, contracted, unequal or irresponsive, causing the case to resemble general paresis. After several weeks or months, improvement gradually occurs and the case may go on to complete recovery, or this may be incomplete, or pass into some other form of mental derangement.

The duration of the psychosis in 11 cases reported by Meyer in which recovery took place was from two months to two years; and in 18 similar cases of mine, from six weeks to two years. Death occurred in 4 of Meyer's cases, after the development of the psychosis, after two days to one month and in 4 of my own after a period of from seven days to four weeks. In the remaining cases reported by Meyer 3 patients recovered but relapsed, 2 made partial recoveries, 1 developed epilepsy, and 4 developed some other form of insanity. In the 10 similar cases of mine 2 patients became epileptics, 2 partially recovered, 1 developed manic-depressive insanity, and 5 passed into dementia.

Kraepelin and Meyer assert that, when dementia follows this psychosis, it is always the result of epilepsy, arteriosclerosis, or alcoholism; and this statement is sustained by the facts found in my cases. Death, when it occurs, is due to exhaustion from continuous muscular movement and persistent insomnia.

ORGANIC DEMENTIA

As has been said, this psychosis may follow acute primary traumatic insanity, or may be the result of traumatic epilepsy, or of cerebral hemorrhage, thrombi, meningitis and abscess due to the same cause. Such a dementia is, of course, permanent in character, and more likely to occur in persons suffering from arteriosclerosis, alcoholism, syphilis or a neuropathic taint. To establish a dementia, then, as of traumatic origin it must appear that it was preceded by one of the conditions mentioned.

IDIOCY AND IMBECILITY

These may in the same way follow any injury which destroys the brain tissue before development, as hemorrhage, thrombus, laceration or abscess; but it is to be noted that the reparative powers at this early age are so great as to make this result very uncommon.

DEMENTIA PRÆCOX, MANIC-DEPRESSIVE INSANITY, MELANCHOLIA, ACUTE DEMENTIA, AND PARANOIA

These have been described as occurring from the shock due to some injury. From the small number of cases said to be due to this cause it would appear that the accident either only called attention to an already existing condition or hastened the development of the psychosis.

GENERAL PARESIS

The relation of this condition to injury to the head is yet a much disputed question. Some writers maintain that it may be directly due to the injury; others that the injury only aggravates the course of an already existing condition (for, as is well known, paresis may develop rapidly after a long latent period), and others believe that the so-called traumatic cases are really ones of acute primary traumatic insanity passing into dementia. The superficial resemblance of this condition to true paresis has already been referred to. In my opinion the two latter views are the most probable. It is easy to understand how such a complex lesion as that of paresis might be aggravated by a cerebral contusion though not caused by it, and how the traumatic cases closely simulate paresis. I myself have never seen a case of true paresis which I was satisfied was of traumatic origin.

29 South Portland Street.

ABSTRACT OF DISCUSSION

DR. M. ALLEN STARR, New York: Three cases of traumatic insanity have come under my observation in which successful operations have been performed for the relief of the insanity. None of these cases corresponded to any of the ordinary types of mental disease as described. In the first case a young man of 21 was subject to sudden attacks of violent headache which culminated in an attack of acute mania, with destructive impulses. These attacks would last from three to five days, then subside, and he would be entirely free from the condition. He had a perfectly good memory which indicated that there was no epileptic psychosis. Dr. McCosh opened the skull over a point of tenderness on percussion, just posterior to the ascending parietal convolution in the superior parietal lobule about its junction with the interior lobule. This patient had a history of having had a fall as a boy at the age of 12, although the symptoms did not come on until he was 14, and he was operated at 21, after this long period of invalidism, and we found a very beautiful angioma that it was perfectly possible to tie off and take out, with complete recovery.

In another case which came under my observation not long ago, a man had been hit a severe blow in the head. He had been perfectly healthy before that time. He was coming up out of a boat and did not notice the projection of the gangway as he came up, and hit his head very suddenly. He was dazed for a moment, and next day he was found to have a slight paralysis of the opposite side of the arm and face that lasted for several weeks and gradually passed off. Then he became subject to sudden attacks of wild maniacal excitement in which he had been homicidal on several occasions. These attacks would come on very suddenly, without warning, and they had occurred from time to time when I saw him for four or five years. The hemiplegia in the meantime had entirely passed away, nor was there any physical evidence of any defect excepting the occurrence of these attacks.

Under the circumstances, every other resource having failed. I suggested that the surgeon cut down on the motor area, or somewhat anterior to the motor area of the brain, and at the level of the middle third, on the possibility of there having been some injury of the frontal region that had encroached on the arm center at the time, and then had healed. We cut down and found a cyst about the size of a pigeon's egg lying right on the posterior part of the second frontal convolution, forward of the motor zone. There had been no epileptic manifestations, by the way, whatever, and it was purely a lucky find. The walls of the cyst were carefully removed, and evidently the man had had a slow hemorrhage occurring from a vein of the pia mater at the time of his injury; and that hemorrhage had organized and gone on to the formation of the cyst. The cyst had lain there and apparently had given rise to occasional symptoms of pressure, probably owing to some variation in the circulation and some occasional condition in the cyst that gave rise to these attacks of mania from which he is now perfectly well.

I will not describe the third case, but I will say that not only in my experience in these three cases, but also in a number of other cases of traumatic insanity, I have seen symptoms of insanity irregular in type, which do not correspond to classical types of insanity as shown in the text-books at all.

DR. A. C. BRUSH, Brooklyn: These cases do not correspond to the classical description in the text-books. To a man dealing as I do with corporations it is embarrassing to have certain text-books put before one which purport to cover the whole ground and yet do not state the truth. This field of litigation is very important, and it is doing more to discredit us than anything in the world, with the general public and the courts, and it is time that our ideas were clearly defined on the subject.

Literature of Obstetrics in Mexico.—N. Leon has been compiling the bibliography on obstetrics in Mexican literature. His compilation has been published serially, running through several numbers of the *Cronica Medica Mexicana*, listing a total of 696 articles or books. The title of each is given in full, with source, the whole arranged alphabetically by authors and concluded in the issue for September 1, 1909.

PELLAGRA IN VIRGINIA

J. H. HEWITT, M.D.
LYNNHAVEN, VA.

In a recent article, Wood[1] makes the statement that no cases of pellagra have been reported from Virginia or Ohio, although these states furnish a large portion of the corn consumed in a section of the country from which he has been able to report a number of cases. That genuine pellagra may occur in Virginia, however, I believe the following case will bear witness:

Patient.—H. A. S., London Bridge, Va., aged 56, white, widower, occupation milling and farming, was born in Charlotte county, Virginia, reared in Pittsylvania county, and remained there the greater part of the time till February, 1909, when he moved to Princess Anne County, Virginia. He had spent a year each in Roanoke and Lynchburg, Va., where financial reverses made him poor. He had also spent three years in Nebraska and then returned to Virginia.

Family History.—The patient's father was killed in an accident at the age of 48; his mother died of old age at 84. Two brothers are living and well. Two brothers are dead; one of "Bright's disease," the other of "brain fever." Five sisters are living and well. One died when 3 years old of whooping cough. There is no history of cancer, tuberculosis, rheumatism, or insanity in any member of the family. The patient's father and two of his brothers always suffered from diarrhea whenever they ate bread made from corn-meal.

Personal History.—During childhood the patient had diphtheria, measles, mumps, and whooping cough. He had typhoid at 18, malaria and gonorrhea at 26, grip at 35. Since 35 he has always been well till the present illness. He has noticed that bread made from corn-meal always disagreed with him, even in childhood, producing diarrhea and intense intestinal pain. His father and two of his brothers, as above stated, were also similarly affected by corn-meal bread, but he has no knowledge that any of them ever suffered with roughness and desquamating of the skin at any time. His average weight is 145 pounds. He uses tobacco and alcohol moderately. He is the father of seven children, all of whom are dead. The second child died at the age of 13. His wife died sixteen years ago. They lived together eighteen years. He denies lues.

Present Illness.—The patient is now a very poor man and for the last three years has been living in cheap boarding-houses or keeping bachelor's quarters in which he did his own cooking. During the latter part of last fall, owing to the scarcity of work and the high price of flour, he was compelled to eat more and more corn-meal. About the middle of last December his present diarrhea began, very mild at first, but slowly and steadily increasing in intensity till about six weeks ago, when he had from ten to twelve movements per day, with agonizing tenesmus and distressful abdominal pain and nausea. For the last month he has ceased to use corn-meal in any form and the diarrhea has considerably abated. Since December he has lost about thirty-five pounds in weight and has been reduced from a robust, virile, workingman to a puny, weak, sickly individual, to whom life itself is almost a burden. About ten weeks ago, while picking strawberries, the back of his neck became red and burned, as if sun-burnt. At the same time he suffered with intense headache which was confined to the region "behind his ears and extended across from ear to ear." This continued for about ten days. During this period the skin on the back of his neck began to peel off. About the same time the skin over the bridge of his nose and the side of his face, after having been red and painful, likewise began to desquamate in small and large dry scales and bran-like particles. About six weeks ago the skin on the back of his hands began to look as if they were blistered, being swollen, red and painful, and scattered vesicles filled with serous exudate were formed. The surface then became quite dry and hardened, cracking at all the joints and in between the fingers. Both hands were similarly affected and about the same extent of surface on each involved. In about a week the skin on the back of the hands, fingers and lower one-third of his forearms began to desquamate in the same manner as that on his neck and nose. About the same time all of the toes of both feet became swollen and red. They burned slightly and itched in a most intense manner. This, however, disappeared within a week and there was never any induration of desquamation of any portion of the skin. About five weeks ago the gums of his upper jaw became swollen and red. There was slight salivation for a few days but this soon disappeared and has not since recurred. Since December he has vomited only once, that he remembers, but has repeated attacks of nausea every day. During the last ten weeks he has had repeated attacks of vertigo; often becomes dizzy on rising from a sitting to a standing position, or on rising from a recumbent position, and everything becomes black before his eyes.

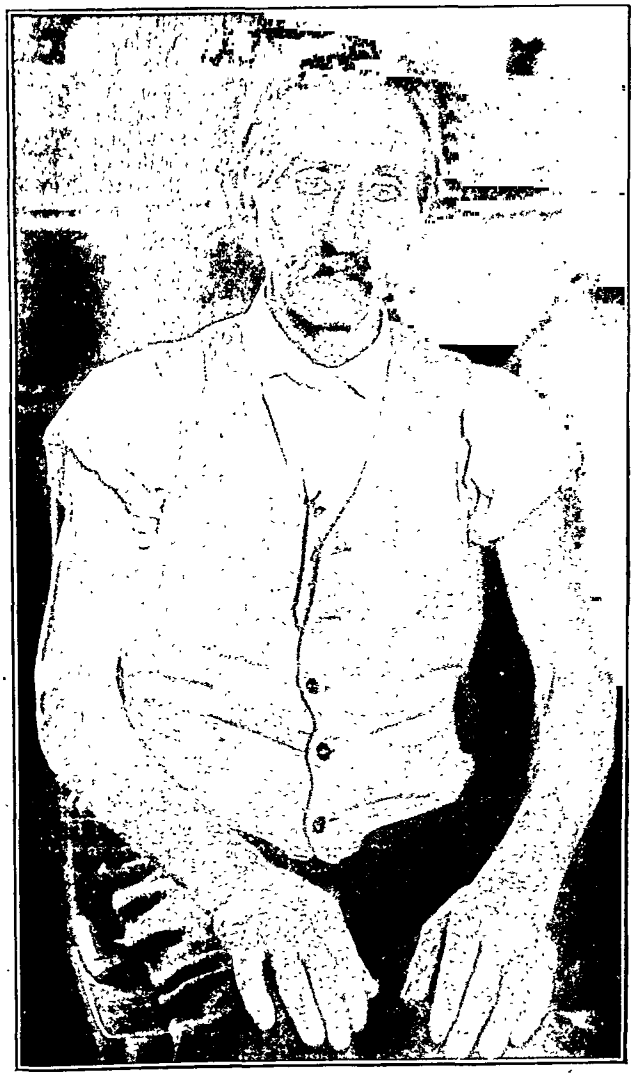


Fig. 1.—Patient with pellagra, showing the apathetic, smile-forgotten expression of the face and the extent of the lesion on the hands.

Examination.—General: The patient is a moderately emaciated white man, well advanced in years, with a very apathetic, listless appearance. He answers questions in a slow, whining monotone. He is sitting up and is able to walk around to a limited extent; however, his gait is slow and he is evidently very weak. He gives a slight groan with each expiration and appears to be in great distress. His hair is lusterless, dry and straight. The eyes react sluggishly to light and accommodation. All of the upper teeth have been removed. The lower teeth all show more or less marked decay. Pyorrhea alveolaris is quite extensive. Respiration is slightly labored. The skin everywhere has a muddy pallor. The heart, lungs and thorax show nothing abnormal. The abdomen is scaphoid in shape. The liver, spleen and kidneys are not palpable. The deep reflexes of the upper and lower extremities are incrased. Plantar stimulation gives a slight dorsal flexion of the great toe. No patellar nor ankle clonus can be obtained. There is no Romberg's sign, but slight tremor on protruding the tongue. The patient gives no history of urinary trouble at any period of his life, though for the past four months he has had to get up once or twice every night to micturate, otherwise, negative. Freshly voided urine shows a specific gravity of 1032; deep amber color; sugar and albumin, negative.

---

[1] Wood, E. J.: Pellagra in the United States, The Journal A. M. A., July 24, 1909, liii, 274.

Skin: Over the back of the neck, extending upward to the hair line and downward to the level of the upper border of the soft shirt collar, the skin is of a dirty rose-pink color and everywhere covered with small and medium-sized patches of dry exfoliating epidermis. This superficial epidermis may be easily removed and no bleeding points remain. The same appearance and condition may be noted on each side of the neck, extending as far forward as the anterior border of the sternocleidomastoid muscle. Similar areas over the cheeks, sides and bridge of the nose, and the lateral aspect of the forehead, fuse and become continuous with these areas on the neck. The symmetrical situation of these lesions on each side of the head is marked. Over each side of nose, especially marked in the region of the alæ nasi, there appears a hypersecretion of the sebaceous glands. The orifice of each gland, filled with grayish-white sebaceous material, gives the skin a white stippled appearance. The surface of the skin over these areas is quite dry and rough to the touch. In certain places there is a small amount of sebaceous exudate attached to the plaques of dead epidermis, giving them the character of thin crusts. Along the lower of the areas on the neck and the upper margin of the areas on the forehead there is a line of intensified brownish pigmentation. The margins of these roughened areas is everywhere sharp and well defined. Symmetrically situated on each side of the neck, just below the lower margin of the roughened area, is a lenticular-shaped area of deeply reddened skin over which the superficial skin appears shriveled. These areas, the patient tells me, have appeared in the last few days and have the same appearance as the large areas when they were first noticed. The mucous membranes of the lips and conjunctivæ are pale but moist. The skin over the chin and the anterior portion of the neck appears pale and slightly tanned, but otherwise normal. Over the sternum, on the right side, there is a lozenge-shaped area, measuring about 5 by 2 cm.; beginning above at the sternoclavicular articulation and extending downward and inward to a level of the upper border of the third rib, there is a brownish pigmented area of desquamating epidermis. On the left there is a similar area but smaller. Symmetrically situated on each shoulder, over the acromial process, the spine of the scapula, and the infraspinous fossa, the skin is roughened, harsh, scaly, and covered with numerous patches of brownish, desquamating epidermis. The skin underlying all of these areas is pale, slightly thinned, and very dry and rough. There are also similar areas symmetrically situated over each deltoid and each triceps muscle. The skin over each olecranon process shows the same appearance as that noted above, i. e., a dry, harsh, desquamating superficial skin and a dry, pale, slightly thinned underlying skin; but after exposure to the sun for a few minutes, as was done when I attempted to photograph the patient's hands, the underlying skin assumed a rose-pink color, similar to that to be described over the hands and arms. The whole surface of both hands, especially the backs of the fingers and hands, and the lower one-third of both arms are everywhere quite rough and scaly. The skin of the dorsum of the hands, wrists and lower portion of the forearms is of a diffuse erythematous rose-pink color. Scattered over these areas are innumerable small and large patches and plaques of dried and desquamating epidermis. Along all the natural furrows of the hands and wrists, at the interphalangeal joints, and in between the fingers there are deep cracks. These cracks, the patient tells me, were much deeper a few weeks ago. They were also at that time more painful and tender and would often bleed after slight injury. Only a few of them now extend through the true skin and they are all healing rapidly. The skin over the sides of the fingers and the backs of several of the interphalangeal joints is markedly thickened and has the appearance of the surface of a saw file. The skin on the palms of the hands is pale but the superficial layer is dry and harsh to the touch. In places it may be peeled off in large thick plaques, leaving a comparatively normal subjacent skin. The line of separation between the affected and the non-affected skin is sharp and well defined.

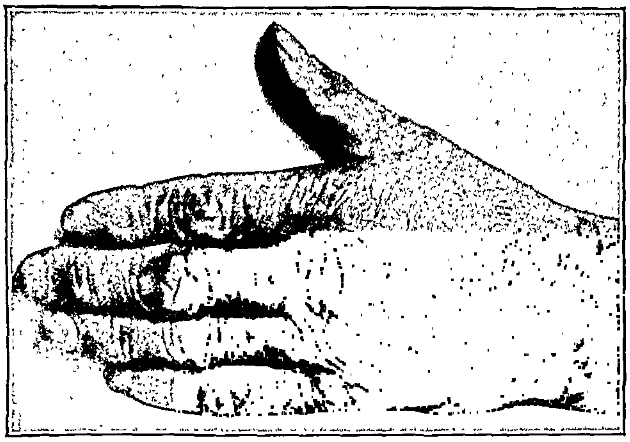

Fig. 2.—Hand of patient, showing the rough, cracked surface and the desquamation of the epidermis.

Mentality: The lady of the house tells me that the patient often has fits of extreme irritability when nothing can be done to please him and he is extremely fault-finding and quarrelsome. He shows complete orientation and can remember dates and events accurately but has to think over many of them for a considerable time. He can perform simple problems in arithmetic but with none of the accuracy or rapidity that might be expected of one who had once controlled a business house with a capital stock of $5,000, as he once did, according to his story. He complains of difficulty in buttoning his shirt and coat, but this is most probably due to the anesthesia produced by the drying and desquamation of the superficial skin over the tips of his fingers.

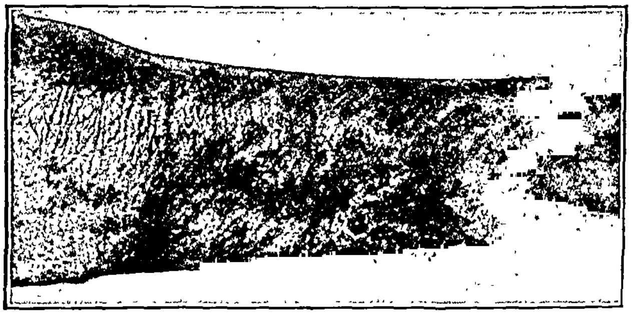

Fig. 3.—Wrist of patient, showing the pigmented border and the sharp line of demarcation between the normal and the unhealthy skin.

Diagnosis.—So far as I can interpret the cases and photographs of this affection that have been presented in the recent literature the group of symptoms and signs in this case point most strongly to its being pellagra. The signs and symptoms, reviewed briefly, are these: (1) A persistent diarrhea, presumably originating from the eating of corn-meal; (2) a subsequent erythema of certain symmetrically situated and well-defined areas of the skin, followed by slight pigmentation, desiccation and exfoliation, accompanied by severe occipital pain, vertigo, and dizziness; (3) a weak mentality and central nervous system. The fact that the patient is now recovering rapidly would place the case in the class called by Thayer[2] "a milder chronic and commonly recurrent malady."

Pellagra has been recently reported[2] from Maryland, and a number of cases have for some time been under observation in North Carolina;[1] accordingly, from a geographic or climatologic standpoint, there is no reason why a certain number of cases should not also exist in this state.

---

[2] Thayer: Bull. Johns Hopkins Hosp., xx, No. 220.

The part played by corn-meal in the etiology of this malady is, of course, still a matter of conjecture. But it does seem to me a point worth consideration that this patient had noticed that the eating of corn-bread always disagreed with him, so much so that he avoided eating it as much as possible and, furthermore, attributed his present condition to this article of food. Moreover, his father and two of his brothers were similarly affected by a corn-meal diet and, likewise, always avoided it. None of them, however, so far as the patient has any knowledge, were ever affected with any cutaneous disturbances similar to his. It would manifestly be very interesting to know if any of the other cases that have been reported can furnish anything to corroborate or disprove the conclusions this case might tend to establish. I am aware, however, of the fact that a case has been reported in which the patient denied ever having eaten corn-bread, corn-flakes, or hominy.

If corn-meal and its consumption has any etiologic relation to pellagra and if wheat retains its present high price, we may certainly expect an increasing number of these cases to appear, particularly, in certain regions of our country where the people are exceedingly poor and where wheat is not a staple product.

PELLAGRA

ITS OCCURRENCE IN THE COOK COUNTY INSTITUTIONS

LEWIS J. POLLOCK, M.D.
Senior Physician, Cook County Institutions
DUNNING, ILL.

In the following paper I wish to report the occurrence of pellagra in fourteen patients of the Cook County Institutions, Dunning, Ill. Eleven were inmates of the Hospital for the Insane, one of the Hospital for Consumptives and two of the Infirmary.

The first case was observed in August, 1908, when the diagnosis of pellagra was as yet not made. With the subsequent occurrence of three other cases presenting the same [illegible] course and fatal outcome, not being [illegible] occurrence of pellagra in the United States, we came to the conclusion that we were dealing with a clearly defined disease. A clue to the nature of these cases was offered in the description of pellagrous insanity in Bianchi's "Psychiatry." From the onset, the next case was thought to follow closely the description of Italian pellagra, but it was not until the inquiry of the South Carolina State Board of Health was addressed to us that the diagnosis of pellagra was definitely made.

In view of the prevalence of pellagra in the Southern states of North Carolina, South Carolina, Georgia, Alabama, Tennessee, etc., and in view of the fact that this disease existed in those states for twenty or thirty years before being properly diagnosed, the importance of its recognition in other parts of the United States is self-evident.

The reports of its occurrence in the Northern states, as accurately as can be determined from the literature and from replies to letters of inquiry concerning its prevalence addressed by C. F. Williams, Secretary, South Carolina State Board of Health, to the superintendents of the state hospitals in the United States, have been limited to the following:

Two cases reported by Gray of Utica, N. Y., and Tyler of Somerville, Mass., in 1864.

Two cases reported by Thayer of Baltimore, Md., in 1909.

One case in Pennsylvania.

Few cases in New York.

One or two cases in Maryland.

This relative infrequency of pellagra in the Northern states gives special importance to its occurrence in Illinois.

Following the numerous recent reports on this condition, the description of the disease and the report of the Cook County cases will be made as concise as possible.

Pellagra was probably first recognized in Spain in 1735, when it was described by G. Casal, who termed the condition mal de rosa. It appeared in Italy in 1750. In 1771 Frappoli called attention to this condition in Lombardy, where the peasants called it pell' agra. About 1810 Marzari called attention to the relation between maize and pellagra, and in 1844 Balardini first suggested that the disease might be due to the ingestion of diseased corn, which view has been confirmed and upheld by Lombroso.

The disease is prevalent in Roumania and Italy; in the latter there are about 100,000 patients, of which, according to Tuczek, 10 per cent. are mentally affected. In Roumania there are about 30,000 cases. The disease is also found in Spain and Upper Egypt, and cases are reported in Austria, Servia, Bulgaria, Africa, Mexico, South America, and lately in the United States.

The first to report pellagra in the United States were Gray of Utica, N. Y., and Tyler of Somerville, Mass., in 1864. Since that time there have been but few reports on this condition until recently. Since the report of Searcy of Alabama in 1907, there have been numerous contributions to the literature. Dr. C. H. Lavinder[1] has reported to the Surgeon-General a conservative estimate of 1,500 cases in the South since 1906.

Aside from the predisposing cause of alcoholism, previous illness, poor hygienic surroundings, poverty, venereal excess, etc., *it is the accepted opinion of most Italian students* that pellagra is a disease caused by the eating of spoiled maize, constituting an intoxication from the toxin produced by the growth of fungi in corn. There has lately been dissenting theories introduced, among the strongest of which is Sambon's, who presents numerous points against the maize theory. Suffice it to say that the etiology and the pathogenesis of pellagra is as yet an open question, but that corn may bear the same relation to pellagra as swamps do to malaria and yellow fever.

The pathology is not characteristic and may shortly be said to consist of changes of cachexia, such as wasting of the adipose and muscular tissue, fragilitas ossium, atrophy, fatty degeneration of the heart, liver, kidney and spleen, abnormal pigmentary deposits in the ganglionic cells, muscles of the heart, spleen and liver. Changes in the intestines consisting of atrophy of the muscular coat, hyperemia and ulceration.

The nervous system shows at times hyperemia, at other times anemia and edema, inflammatory changes in the coverings, degeneration in the lateral columns in the dorsal region and of the posterior columns in the cervical region. Lombroso says that the spinal cord changes remind one of incipient tabes.

The skin lesion shows (1) congestion, (2) thickening pigmentation, (3) atrophic thinning.

---

[1] Lavinder, C. H.: Public Health Reports, June, 1909, xxiv, No. 25.

Of the symptoms, those belonging to the alimentary tract, skin and nervous system are the most prominent, but will here be but briefly considered. The disease usually begins with gastrointestinal disturbances, followed by erythema of the skin, and later by nervous manifestations. The gastrointestinal disturbance manifests itself by nausea, sometimes vomiting, ptyalism, loss of appetite and, most important, by diarrhea. Stomatitis is one of the most marked and constant symptoms. The mucous membrane is red, apthous ulcers develop and patches of macerated epithelium exfoliate, leaving a raw surface beneath.

The cutaneous symptoms are characteristic; the lesion consists essentially of an erythema appearing symmetrically and usually on the exposed parts of the body, especially the extensor surfaces, backs of the hands, forearms, neck, etc. It begins with redness and some puffiness. The redness becomes more cyanotic and is sharply demarcated. The surface of the skin becomes dry, harsh and scaly, exfoliating in flakes or scales. In some cases bullæ occur and with severe desquamation leave large denuded surfaces. The skin afterward assumes a dark color, from plum to brownish black; cracks and fissures form. After desquamation the skin appears thin and atrophied, with superficial wrinkles, at times having an appearance of striæ. The lesion is always sharply demarcated and on the hand usually leaves the distal phalanges uninvolved, ending at about the middle third of the forearm, seldom extending to the flexor surface.

Among the mental and nervous symptoms may be mentioned vertigo, neuralgia, partial paralysis, tetany-like conditions, tremors with variability of deep reflexes from increased to diminished and lost. Psychical manifestations usually take the form of melancholia, but maniacal attacks may occur.

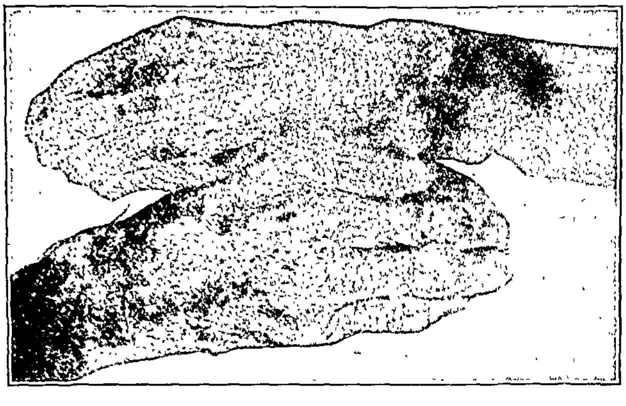

Fig. 1.—Hands of patient 13.

The disease is essentially of chronic nature, in some cases lasting for twenty years, interspersed with spring exacerbations; it is met with in acute and chronic conditions. The acute, which is most commonly observed in the United States, is often fatal, running its course in a few weeks, but probably should not be called "acute pellagra" inasmuch as it is possible that it is but an acute exacerbation of a chronic process.

In the diagnosis of this condition there may be considered the various grain and food poisonings, lichen and similar skin lesions, scurvy, leprosy and beriberi, etc.

The prognosis is usually serious and the mortality in the United States unusually high.

The treatment up to date has been of little avail. Removal of corn from the diet and substitution of a nutritious diet of medicinal remedies—all have been of small benefit. Arsenic, quinin, strychnin and iron have been used; of late atoxyl has been vaunted as a cure, but the probability is that it, too, is of little avail.

From the cases arising in this institution the following interesting facts may be determined:

The entire number was fourteen:

Females, 10; all insane.

Males, 4; 1 insane; 2 in the poorhouse, 1 in the hospital for tuberculosis.

The duration of the fatal cases averaged 37 days.

The duration in the remaining cases averaged 34 days.

The nativity was as follows:

United States	5
England	1
Ireland	3
Bulgaria	1
Germany	2
Denmark	1
Unknown	1

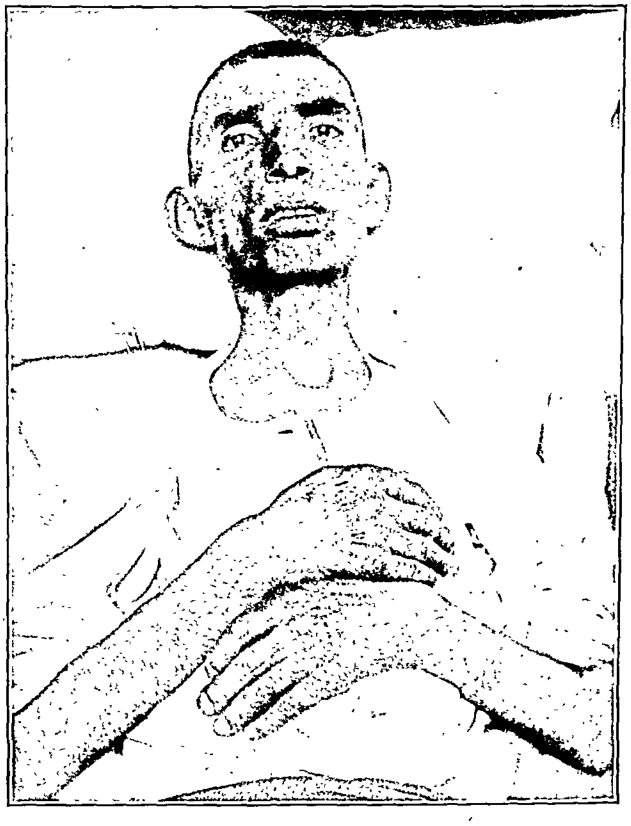

Fig. 2.—Patient 14.

Of those foreign, the Bulgarian was in this country six months. The others ranged from eight to thirty years. They had been confined in the institution from one to twelve years.

Their psychoses at time of admission were as follows:

Dementia paralytica	3
Alcoholic	1
Dementia præcox	2
Paranoia	3
Acute confusional	1
Melancholia	1

The symptomatology has been fairly uniform, all presenting the syndrome of stomatitis, dermatitis, and diarrhea. The cases had an onset with some malaise, indifference, and loss of appetite; they exhibited during the course some ptyalism, progressive weakness, choreiform movements, mental symptoms of depression to stupidity, and increasing dementia, refusal to eat, and in some cases dysarthria and dysphagia. Of the patients who died, one died of apoplectiform convulsions of dementia paralytica, one in a low muttering delirum, associated with stupor and choreiform movements, one of respiratory failure, one probably of pneumonic tuberculosis, and one of inanition of carcinoma of the stomach; the others of exhaustion.

The treatment in the first six fatal cases did not include arsenic. In the later cases arsenic was given hypodermically in the shape of Fowlers solution, omitting the compound tincture of lavender. The course in these later cases has not been so severe and the results are slightly promising.

The pathology of those cases in which we were able to obtain postmortem examinations will be described for the most part in gross as we have as yet not examined sufficiently fully the microscopic findings to report in this article.

Case 1.—L. F., female, admitted May 29, 1907, aged 38, born in the United States. Physical condition on admittance good. Psychosis, paranoia. Previous history negative. Mental status previous to onset of pellagra that of systematized delusions of persecution by spirits and hallucinations of hearing.

May 6, 1908: Patient developed a dermatitis of hands, face and neck. With the onset of the skin condition the patient became irritable and suspicious and failed physically rapidly.

Aug. 15, 1908: Skin had become brawny and thickened, covered with whitish scales. Patient had become untidy.

Aug. 24, 1908: Patient developed a slight endocarditis. Breath was fetid; mouth and teeth well covered with scaly layer of putrid material. Patient had a slight evening fever; died of acute endocarditis.

Case 2.—A. C., female, admitted 1903, aged 34, born in the United States. Former admission in 1902. Physical condition on admission good. Psychosis paranoia. Mental state that of systematized delusions and poor emotional control; vicious and revengeful. Until 1908 condition remained unchanged.

Oct. 23, 1908: Patient had been failing lately and had developed frequent attacks of diarrhea. A scaly condition of the hands had appeared. Patient was losing weight; had become untidy and greatly demented.

Oct. 29, 1908: Dermatitis was now well marked, symmetrical, hard, reddened and scaly, having sharply defined borders, appearing on the backs of the hands and neck. Patient refused food and had a severe stomatitis.

After presenting a progressive course of increasing weakness, diarrhea, stomatitis, with increasing dementia and untidiness, patient died on Nov. 19, 1908, of exhaustion.

Case 3.—M. R., female, admitted May 24, 1906, aged 32, born in Ireland; physically, suffering with chorea; otherwise in good condition. Psychosis acute confusional insanity. Mental condition that of restless confusion.

Sept. 28, 1908: Patient had been failing in flesh lately; had become very destructive and much demented. Skin showed a dermatitis of hands and face which was symmetrical in distribution. After running a course of increasing weakness with diarrhea and dermatitis, patient died on Oct. 10, 1908, of exhaustion.

Case 4.—M. A., female, admitted April 9, 1908, aged 45, born in the United States. Physical condition that of paresis. Psychosis dementia paralytica.

May 26, 1908: Patient failing mentally and physically; was generally weak, dull and apathetic.

Oct. 27, 1908: Patient had many stuporous attacks lately; had become very untidy. A symmetrical dermatitis developed on dorsal surfaces of the hands, which were hardened, pigmented and fissured. The face showed a marked seborrheic condition; a vaginitis was likewise present.

Nov. 11, 1908: Patient had developed a severe diarrhea and stomatitis; had irregularly occurring attacks of vomiting and was gradually failing.

Nov. 29, 1908: Patient had an apoplectiform convulsion of the right side; developed edema of the lungs and died.

Case 5.—M. F., female, admitted March 1, 1897, born in Ireland. Physical condition on admission, good. Psychosis melancholia. History negative except for the patient having used a great amount of alcohol.

December, 1905: Physical condition good. Patient had numerous delusions of persecution.

Feb. 27, 1909: Patient had been failing in health lately and had become rather unsteady in her gait.

March 20, 1909: Patient had developed a dermatitis of both hands, the dorsal surfaces of which were symmetrically hardened and fissured. Patient was becoming more demented.

March 27, 1909: Patient was in a semistuporous condition; had marked dysarthria and dysphagia, marked stomatitis, teeth covered with sordes. Ptyalism was marked. Patient exhibited incoordinate movements of upper extremities and an inability to stand. There were no paralyses; knee-jerks were absent; plantar reflexes normal, abdominal reflexes absent. Pupils were equal; reacted to light and accommodation. Electrical reactions were unchanged.

March 31, 1909: Patient had been having a slight evening fever with rapid pulse which was compressible and irregular.

April 14, 1909: Patient developed a diarrhea. Dermatitis was more marked; the skin was fissured, desquamation taking place, exposing raw red surfaces.

April 19, 1909: Patient, after having failed rapidly and exhibiting marked incoordinate movements of arms and legs, died.

Case 6.—L. C., female, born in United States, aged 40, admitted May, 1904. Psychosis dementia præcox. Previous history negative. Physical condition on entrance negative. Psychically a low grade idiot.

January, 1908: Patient in fair physical condition.

June 7, 1909: For the past two weeks patient had developed a dermatitis of both hands, face and neck, which began as an erythema, becoming hardened, scaling, leaving the exposed surface moist. The lesion was symmetrical, involving the dorsal surfaces of the hands and wrists and a butterfly-like involvement of the face spreading from the nose and one patch over each sternocleidomastoid. The patient was in poor general condition; had a general adenopathy. Heart and lungs negative. Nystagmus on lateral movements of the eyes. A double Oppenheim and Gordon but no Babinski. Knee-jerks were increased; a double ankle-clonus and knee-clonus were present. Active movements of both upper and lower extremities were negative. Passive movements were negative except for a double Kernig's sign.

June 9, 1908: Patient, after lying in a semicomatose condition for the past two days, died of respiratory failure, after having once been resuscitated by artificial respiration.

Case 7.—E. S., female, born in Germany, admitted October, 1908, aged 28. Physical condition on admission good. Psychosis dementia præcox. General mental status previous to onset of pellagra that of depression, refusal to eat, and fear.

June, 1909: Patient had become more demented and was fed with great difficulty. Physical condition about the same.

July 5, 1909: Patient had developed a symmetrical dermatitis of the dorsums of both hands and wrists. The lesion over the hands consisted of a sharply demarcated thickening and redness and scaling, leaving a glazed surface exposed. There was a similar lesion over the back of the neck. A moderate stomatitis was present, consisting of excoriations with the presence of several small whitish ulcerations. The epithelium was piled up and desquamating. The tongue was red and glazed, the papillæ were prominent. Heart and lungs were negative. Patient had slight diarrhea and was very weak. Mentally, she was much depressed and cried a great deal.

July 12, 1909: Patient had during the past week been failing rapidly. The stomatitis was worse, the dermatitis stationary. Ptyalism was marked and dysphagia and dysarthria were present. Patient complained of burning pain extending from her throat to her stomach; had a slight evening fever.

Aug. 1, 1908: Patient was beginning to improve; stomatitis was less severe. The slight diarrhea that was present had disappeared and the skin lesion was fading away.

August, 1909: Patient continued to improve; diarrhea had disappeared, stomatitis subsided and patient was much more cheerful, taking nourishment willingly.

Case 8.—F. S., female, born in the United States, admitted June, 1908; aged 30; married. Physical condition on admission good. Psychosis *dementia paralytica.*

June, 1909: Patient complained of pain in the stomach and loss of appetite; had a slight redness of the skin of the hands.

July, 1909: Patient had a symmetrical dermatitis of both hands, one patch on each side of the neck, moderate stomatitis and a slight diarrhea. After running a slight course of diarrhea, with progressing weakness, she began to improve, the depression being replaced by exaltation, the skin lesion disappearing and the stomatitis subsiding.

Case 9.—M. O'D., female, admitted April, 1909, aged 32, born in England. Physical condition on admission poor; marked anemia. Psychical diagnosis, dementia paralytica. General mental condition before onset of pellagra, marked depression, confusion and emotional instability.

July 1, 1909: Patient had become very resistive; refused food, had failed physically.

July 5, 1909: Patient had developed a symmetrical dermatitis of both hands and wrists; a similar condition was present on the sides of the neck. There was a marked stomatitis; slight diarrhea was present. Knee-jerks were exaggerated. Patient refused food and had to be tube-fed. Lungs showed slight dulness in both apices with roughened breath sounds but no râles.

July 18, 1909: Patient was rapidly failing. Stomatitis was very severe. The skin lesion was, however, becoming less marked. All the glands were enlarged. The diarrhea had subsided. Patient remained resistive and refused food.

July 29, 1909: After having progressively failed, despite the improvement in the condition of the skin and mouth, patient had developed signs of a pneumonic infiltration of the right lung with high temperature, rapid respiration and rapid weak pulse, and died on Aug. 1, 1909.

Postmortem Examination.—An extremely emaciated woman. Inguinal glands enlarged; abdominal cavity free from fluid; adhesions surrounding gall-bladder extending to the pylorus, duodenum and transverse colon; adhesions between spleen and parietal peritoneum and between uterus and rectum. Left pleural cavity free from adhesions; right pleura firmly adherent to lung; pericardial cavity contained 15 c.c. of clear fluid; left heart contained a goose-fat clot. Heart practically negative. Lungs: Right upper lobe showed solidification, with old cavity formation. The wall of this was in some places gangrenous and in others cheesy; and the remainder of the lobe contained a large amount of fibrous tissue. The middle lobe and lower lobe showed marked consolidation. The left lung was emphysematous and contained patches of fibrosis. Liver showed some fatty changes. An accessory spleen was present; spleen showed scattered hemorrhage spots. Pancreas was negative. Kidneys were very pale. 260 gm.; glomeruli white and glistening. Stellate veins showed prominently; pyramids pale with considerable fibrous tissue. Aorta showed several ulcerated plaques in descending portion of the arch. Small intestines showed Peyer's patches to be rather plain. In the large intestine the mucosa was injected, otherwise negative. The mesenteric glands were enlarged. Left ovary cystic. Dura mater negative. Small amount of cerebrospinal fluid; no granulations in the fourth ventricle; very little edema of the pia mater. Along the posterior border of the dura from the third dorsal to the mid-lumbar was collection of half-organized material, yellowish in color, with several small hemorrhage spots.

Case 10.—M. W., female, admitted March 8, 1908, aged 46, married, born in Germany. Physical condition on admission fair. Psychosis paranoia. History negative.

Dec. 9, 1908: Patient showed on examination a partial heart-block and an infiltration of both apices. The sputum, however, did not show the presence of tubercle bacilli.

Aug. 6, 1909: Patient developed a symmetrical dermatitis of both hands, with the onset of malaise, loss of appetite and stomatitis. Patient also had a slight diarrhea.

Aug. 13, 1909: The patient was greatly improved. The skin lesion was clearing up and the stomatitis had disappeared.

Case 11.—J. McC., male, admitted June 1, 1905, aged 40, born in Ireland; lived in the United States for twenty-two years. Physical condition on admission good. Psychosis alcoholic insanity. History negative, except for being an excessive alcohol user and having had caisson disease several times. Patient after admittance had an annual attack of diarrhea, not of great severity and lasting but a short time.

July 29, 1909: Following a slight attack of diarrhea, patient developed a slight redness and scaling over the knuckles of both hands. This lesion extended over the dorsal surfaces of both hands and, although not involving a great area, the distribution and its typical appearance left no doubt as to the diagnosis of pellagra.

Aug. 15, 1909: Patient was much better, the skin lesion was disappearing and the diarrhea had subsided.

Case 12.—W. G., male, patient of the poorhouse, admitted 1902, aged 60, born in Denmark. Previous history negative.

May, 1909: Patient developed diarrhea which lasted off and on until July 15 when he noticed a scaling of the backs of both hands. For the following three weeks the diarrhea was of very severe nature; the dermatitis increased in severity and stomatitis developed.

Aug. 8, 1909: The dermatitis was symmetrical, involving the dorsal surfaces of both hands and wrists; there was scaling and thickening. The diarrhea was not so severe and patient was comfortable.

Aug. 21, 1909: Patient was up out of bed; the dermatitis had disappeared, leaving a slightly pigmented, scaly skin; diarrhea was absent.

Case 13.—F. B., male, poorhouse patient, admitted Aug. 11, 1909, in a semicomatose condition, suffering with pellagra; aged 65; painter by occupation. Nativity unknown.

When admitted patient had a symmetrical involvement of both hands and arms by a dermatitis characterized by a brawny induration and redness with some scaling. The patient stated that previous to his admission he suffered with loss of appetite and abdominal pains. Since that time he had had loose but infrequent bowel movements, is failing rapidly and is in a very clouded state of mind. Besides the lesion on his hands there is a slight abrasion of skin over both ankles. He has marked rigidity in both upper extremities and his movements are decidely incoordinate. Knee-jerks are exaggerated, elbow-jerks and wrist-jerks are exaggerated.

Case 14.—S. J., male, patient in the Hospital for Consumptives; Bulgarian; in the United States seven months; admitted to the institution June 18, 1909; aged 38. About three weeks after admission to the hospital it was noticed that the patient had a symmetrical dermatitis of the dorsal surfaces of both hands and wrists which were red, rough and swollen. There was also present a well-marked stomatitis and salivation. The tongue was red and the papillæ were prominent. The patient was suffering from carcinoma of the stomach and showed an abdominal scar from an operation. He could not retain his food and was rapidly failing.

He died Aug. 3, 1909, of inanition from carcinoma of the stomach.

Postmortem Examination.—This showed cyanotic induration of both lungs with areas of bronchopneumonia. The stomach, large and small intestines and the spleen and liver were matted together in a mass by old and very firm adhesions. When these were cut through, there was found a large medullary carcinoma of the stomach involving the larger part of the anterior and posterior surfaces and the curvatures of the stomach, and surrounding and almost occluding the pylorus. The liver, kidneys and intestines, heart and spleen were negative. The cerebrospinal system was likewise negative to the naked eye.

In conclusion, it may be proper to mention a few of the differences pointed out by Babcock[2] between the pellagra of the United States and the Italian pellagra; in the United States the notable points are:

1. Overwhelming number of women attacked.
2. Great mortality of the disease.
3. Invasion of unexposed portions of the body by the dermatitis.

Recognizing the futility of treatment and the prevalence and apparent progression of pellagra in the United States and realizing the enormous food value of corn, it can readily be seen that the subject is one of greatest importance and deserves the deepest study and research. I am indebted to much of the recent literature on this subject for material for this report. A complete bibliography of the literature in the United States may be found in the Public Health Report of June 18, 1909.

LAKE MICHIGAN WATER FOR DRINKING PURPOSES*

W. A. EVANS, M.S., M.D.
Health Commissioner of the City of Chicago
CHICAGO

Lake Michigan occupies a hole scooped out by glacial ice. It is not a natural valley, and in consequence the rivers which drain into it are short and discharge very little water. This is true of the south end and the west shore. On the east shore the St. Joseph, Grand, Muskegon and Manistee are fairly long and carry a fair volume of water. The first two of these drain rather populous areas and their waters reach the lake quite polluted. The banks are seldom sloping and the drainage of storm water does not run directly into the lake except for the distance of a few feet back from the water-line. These factors protect the lake against pollution and therefore argue for the use of its waters for drinking. It is a soft, fresh water and cold.

The other side is this: Counting Chicago, 2,000,000 people either live on the shores or so near thereto that their sewage reaches the lake after a short flow. Just now this population is increasing at the rate of 100,000 a year. In no single instance is any of this sewage properly treated before being discharged and in but few instances is it treated at all.

The tonnage of Lake Michigan shipping is very heavy. The ships carry both freight and passengers. The excursion business between Chicago, Milwaukee, St. Joseph, Benton Harbor and Michigan City is very heavy. A single ship will carry from a few hundred to a few thousand passengers, and the water intakes are usually steering points. Near the water intakes are the points of maximum discharge of feces and urine, as none of these ships have holding devices, or rules as to the closing of closets, and the zones around the intakes are not restricted navigation zones. These waters are more dangerous than salt waters, in that the same water is used for sewage, navigation and drinking purposes. They are less dangerous than ocean waters in that we do not have the shore and wharf pollution action of the tides. The soft waters differ from the salt waters in their action on sewage and different trade wastes. Our fresh water *per se* has no restraining action on the growth of bacteria nor does it modify the chemistry of materials deposited therein.

The Chicago sewage from the south line of Evanston to Eighty-fifth Street on the south now flows into the drainage canal and thence ultimately into the Gulf of Mexico. South of Eighty-fifth Street we now have about 150,000 people whose sewage flows into the Calumet River and then after a short flow into the lake. This sewage is not purified before it is discharged into the river. The same stream also discharges the sewage of Hammond, Ind. (20,000); Whiting, Ind. (10,000); East Chicago and Indiana Harbor (20,000); Gary, Ind. (10,000). On account of the rapid growth of these just-over-the-line sources of contamination, it is safe to say that within five years the polluting popoulation will be 200,000. If we add to that the Calumet Valley population in Illinois, in five years we have 400,000 people. For all of these reasons raw sewage must be kept out of *Lake Michigan.*

The normal water of Lake Michigan twenty miles from shore contains eight bacteria per c.c. and no colon bacilli. There are no uniform currents in the south end of Lake Michigan. The surface current always flows with the wind. A flow of five to seven miles is not enough to purify a large volume of sewage. The time required for a flow of this distance is not enough for purification. The oxygen content of the water is not high enough to purify in this length of time. The saprophytic bacteria are less and less active as the medium is diluted with fresh water. Though a sewage stream holds together quite definitely for three to five miles, wave action limits the efficacy of sedimentation. There is not much fauna and still less flora in these waters.

Generally speaking, these soils of the communities just mentioned are underlaid by a deep stratum of strong sulphosaline water unfit for general drinking purposes. The shallower soil strata do not yield water enough to sustain large populations. The streams to the west and south are altogether insufficient for water purposes. The streams on the east shore are highly polluted. There are no mountains or other high places even fairly satisfactory for water reserve purposes. The waters of Lake Michigan must furnish the drinking-water for these large and growing cities. Therefore the waters must be kept pure.

Chicago has had a typhoid death rate of over 175 per 100,000. Last year it fell to 15.5. That was the lowest in the history of the city. The first five months of this year are lower than the corresponding portion of last year or any other year. The typhoid death rate of the other Lake Michigan cities is high—higher than the American average. The Milwaukee average for five years (1904-1908) was 21.9 per 100,000; Michigan City goes to 40; Hammond, Whiting, East Chicago and Gary range around 70, and some years 90 to 140. These are illustrations of averages around the lake. Escanaba, Grand Rapids, in Michigan, and Sheboygan in Wisconsin average quite high. Waukegan and Racine are far above the average. Therefore the condition is not remote and to be dreamed about. It is immediate and to be acted on.

Lake Michigan is the common charge of the national government, the state governments of Wisconsin, Illinois, Indiana, Michigan, and also of the large centers of population located on the shores.

Acting on a conception of these responsibilities in May of 1908 the Mayor of Chicago asked for the appointment of members of the Lake Michigan Water Commission on the following basis:

	Representatives.
The Public Health and Marine-Hospital Service	1
The Engineering Corps of the War Department	1
The State of Wisconsin	1
Milwaukee	2
Illinois	1
Chicago	3
Indiana	1
Indiana cities, located on Lake Michigan	1
Michigan	1
Grand Rapids, Mich.	1

The commission is now composed of Major Judson, Mr. Hill and Professor Sackett, engineers; Professors

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Bartow and Barnard, state chemists working especially on water surveys; Dr. Gehrmann, bacteriologist; Dr. Young, Dr. Bading, Dr. Sutherland, Dr. Shumway, Dr. Evans, national, state and municipal health officers; and Mr. Becker, ex-mayor of Milwaukee. Lack of appropriations in Michigan have made it necessary for Dr. Shumway to withdraw.

Right speedily the importance of this matter impressed itself on the Chicago Association of Commerce. They called a meeting of representatives of the city governments and business bodies of the various towns located on or near the lake. Fifty-six cities responded. An organization was perfected. The object of this organization is to secure popular and governmental support for the policies advocated by the commission. The first body is for research; the last is to make effective the work of the first. This last organization is the Lake Michigan Sanitary Association. Out of these two organizations have grown two other loose organizations. The towns of northern Indiana have had joint meetings of their city governments and business bodies, first, to advance the study of their sewage disposals and water supplies, and, later to find remedies or a remedy, for up to now, at least, all of the towns are joining in a single movement. The towns north of Chicago, to wit, Evanston, Wilmette, Kenilworth, Winnetka, Glencoe, Highland Park, Lake Forest, Lake Bluff, North Chicago and Waukegan have united to study their situation.

The method of the Lake Michigan Water Commission is to hold about four meetings a year to which reports will be made. Up to now the meetings have been devoted largely to the study of existing conditions. We are just beginning to discuss remedies. The investigations are done by the state and municipal boards of health. Four meetings have been held. The following are the subjects treated in the first volume of reports:[1]

Call for the Commission.
  Letter of Dr. Evans to Mayor Busse.
  Letter of Mayor Busse to the Chicago City Council.
  Action of the Chicago City Council.
  Letter of Mayor Busse to Administrative Officers.
Minutes of the meeting of April 18, 1908, at Chicago, Ill.
Articles of organization.
Minutes of the meeting of May 27, 1908, at Grand Rapids, Mich.
Minutes of the meeting of Sept. 10, 1908, at Milwaukee.
Minutes of the meeting of Jan. 23, 1909, at Indiana Harbor, Ind.
Report on Water Conditions in Michigan, by Dr. Frank W. Shumway.
Report on Water Conditions in Indiana, by Dr. W. A. Evans.
Report on Water Conditions in Wisconsin, by Dr. Q. O. Sutherland.
Report on Water Conditions in Illinois, by Dr. Edward Bartow.
"Currents in Lake Michigan," by Major W. V. Judson.
Extracts from paper by J. A. Amyot.
"Sewage Disposal Problems," by Lederer and Hill.
"Investigation of a Typhoid-Fever Epidemic at Sheboygan, Wis.," by J. T. B. Bowlles.
"Methods of Analysis," edited by Edward Bartow.
Report of Conditions of the Chicago City Water-Supply, by Dr. J. F. Biehn.
Report of Milwaukee City Water-Supply, by W. V. Judson.
"Control of Shipping," by Dr. G. B. Young.
"The Character of the Water-Supply of Michigan City," by H. E. Barnard and J. H. Brewster.
"The Sanitary Condition of the Southern End of Lake Michigan Border—Lake County," by H. E. Barnard and J. H. Brewster.
Report on State Control of Waterways, by Dr. Frank W. Shumway.
Report on a Filtration Plant at the Union Stock Yards, Chicago, by Dr. Adolph Gehrmann.

The investigations of existing conditions relates to:

1. The typhoid death rate (mortality and morbidity).
2. The diarrheal rate in adults other than tuberculous diarrheas (mortality, but principally morbidity).
3. The degree of organic pollution of the waters.
    - (a) In the taps.
    - (b) At the intakes.
    - (c) At various points in the lake.
4. The degree of bacterial pollution at
    - (a) General; (b) colon.
        - (a) The taps.
        - (b) The intakes.
        - (c) Various points in the lake.
5. The location of the intakes.
6. The location of the sewer outfalls, especially in relation to the water intakes.
7. The direction of Lake Michigan currents.
8. The purifying power of Lake Michigan water *in situ* and in the mains.

The commission is just beginning to study methods of sewage purification and the problems of the cities.

As usual Indiana leads. The report from Indiana is the most comprehensive and convincing of which I have any knowledge. The reports from Chicago are complete, but the report from the rest of the state is fragmentary. The Wisconsin reports are next in completeness. Michigan data are least complete. Few Michigan towns get their water out of the lake; many put their sewage in and several take their water from bodies of water that are practically portions of the lake.

Studies made by these cooperating bodies have demonstrated several things. Other things seem probable though not proved. As a result of study of the conditions largely gained from the work of this commission, I hold the following opinions:

1. Lake Michigan water twenty miles away from large sewer outfalls is good, safe drinking-water and excellent in quality.

2. On account of the large volume of water, its low chemical content, and its temperature, it will take care of shore population much in excess of that now existing.

3. The present conditions of the shore waters near all sewered towns are such as to render their use for drinking purposes dangerous.

4. South of an east-and-west line passing through Seventy-fifth Street in Chicago to a similar point in Indiana (an area of nearly 100 square miles) the water is either all so polluted or so frequently and so easily made so that no city should take its water-supply from it and no boat should be allowed to fill its drinking-water tanks from it.

5. There are no constant currents in Lake Michigan.

6. The currents in Lake Michigan are due to the direction of the wind. There is always a surface current with the wind and usually a deep current opposite to the direction of the wind.

7. Irregularities in shore contour, for example, bays or promontories, at times will operate to protect an intake; at other times will have no influence on the water at the intake; at times will operate to foul such water, according to the direction of the wind. For example, a bay protected by a natural or artificial promontory on the north, with the wind in one direction, will have bad water pushed out and good water pushed in; when the wind is in another direction the bad water would eddy around the intake.

---

[1] Now ready for distribution.

8. In the Lake Michigan area there are no prevailing winds.

9. In Lake Michigan there are no prevailing currents.

10. As storms habitually stir Lake Michigan to a depth of 20 feet, frequently stir it to a depth of 40 feet and occasionally stir it to 60 feet, purification by sedimentation is not effective in water less than 50 feet deep in Lake Michigan.

11. As the highly effective saprophytes are not abundant in Lake Michigan, purification is by oxidation, dilution and sedimentation.

12. Therefore the rapidity of purification is not as great as it is in fouler waters with a high saprophytic bacterial count.

13. A flow of seven miles in Lake Michigan is not sufficient for the purification of a massive amount of sewage.

14. With a fairly high and steady wind sewage streams retain quite definite boundaries for several miles.

15. A flow of one mile in the lake is of greater purifying power than a like flow in a stream because of (a) the time required; (b) dilution. It is of lesser power because of (a) the less saprophytic bacterial count; (b) less oxygen absorption. Weighing both equations, one mile is more efficient in the lake, but a forty-mile requirement of river flow is not equaled by a one-mile lake flow.

16. Massive amounts of sewage containing much floating material will sometimes hold together in a definite lake stream for twenty miles.

17. No town should place its water intakes within 1 mile of the sewer outfall of a town of 2,000 inhabitants. This distance should increase *pari passu* with the number of inhabitants using the discharging sewers, other things being equal.

18. Dumping should not be allowed in water less than sixty feet deep in Lake Michigan.

19. Government navigation regulations should keep ships a certain distance from water intakes at all times. They should specify holding provisions, with dumping control on all streams. They should specify zones from which ship drinking-water should not be taken in all bodies of fresh water.

20. Properly controlled, Lake Michigan water will always be safe for drinking purposes.

21. Under present conditions no town is justified in using Lake Michigan water from a point nearer shore than one mile.

22. Large cities emptying their raw sewage into the lake should not take their water nearer any sewer outfall than ten miles.

23. What these states and cities bordering on Lake Michigan are trying to do should be done by the national government for the chain of lakes.

Growth of the Child.—Suitable conditions are absolutely essential to healthy growth, and are more important during infancy and childhood than even at any later period. We must allow time for growth, and not crowd back into childhood exercises suited only to more mature bodies and organs. The mental exercise which is play for the boy may be labor for the young child, and child-labor should be prohibited in our schools. Finally, organs grow and develop successively; first the visceral, vital organs; then the muscles; last of all the higher centers of thought and feeling in the brain. Our systems of education must conform to this order. That system is best and wisest which furnishes the conditions and stimuli needed at each stage to promote the growth or development of the organs most rapidly advancing during that epoch.—J. M. Tyler, in *Hygiene and Physical Education.*

THE ECONOMIC VALUE OF PROTECTING THE WATER-SUPPLIES *

HAROLD B. WOOD, M.D.
PHILADELPHIA

To conserve watercourses means to retain these resources in their natural condition, or in that condition which gives the greatest safety and utility to man. The pollution of a water-suppply is as unnecessary as the wanton butchering of wild animals or the reckless destruction of a forest; in either case the resource is partially or wholly obliterated, and the waste tends to destroy the available livelihood and comforts of the people. A polluted watercourse is not a natural stream.

Municipalities are not the only factors which are accountable for the pollution of public water-supplies. The influence of small villages, individual homes and factories on stream contamination needs more attention. The cities with more people and factories to a given area produce more pollution than the towns with their more numerous cesspools, yet the bacterial contamination is apt to be relatively less with a city, owing to the bactericidal activity of many factory wastes. The presence of disinfectant chemicals in sewage or in drinking-water is strictly objectionable if the sewage or water is to be subjected to filtration. Although in rural districts the more numerous privies cause relatively a less amount of direct stream contamination, the danger of pollution from individual houses can not be overlooked. That there is a great danger from rural communities is attested by the large epidemics which have been traced to individual cases of pollution. In the typhoid epidemics at Butler, Plymouth, New Haven, Nanticoke and Reading there were collectively 3,929 cases, with 361 deaths, resulting from the careless treatment of the discharges of but five individual patients.

The story of damage from epidemics resulting from polluted water is too well known to require repetition, save perhaps for an enumeration of the ways in which the pollution may occur, that the individual contaminating points may be sought and the danger averted. Epidemics from water-supplies result from contamination by various factors: the use of a raw water into which is continually discharged the sewage of other towns, as occurred at Pittsburg, Lawrence and Philadelphia; a city drinking the water of a lake which has become its own cesspool, as did Chicago, Cleveland and Burlington; pollution of the water by the wastes of individual houses, institutions or factories, as at Plymouth, and pollution from privies situated directly over the streams or on the banks, as at Ithaca, or indirect pollution of the stream after the offending matter has been deposited on the surface of the ground or in wells, later gaining access to the watercourse by the washing of rain or seepage through ground seams. In some instances epidemics originate through criminal thoughtlessness when a town has been already supplied with pure or purified water. A water-pipe laid through a polluted pond may become sufficiently disjointed to permit admission by the infected water, as occurred at Baraboo, Wis., and Palmerton, Pa. The admission of polluted water to a pure city supply at any time is inexcusable. Epidemics have originated at times of fire (Lawrence), through failure of valves to operate (Wilkinsburg, Pa.), when the ordinary supply was judged to be insufficient and no public warning was given of the substitution (Newburyport), or when polluted water was furnished temporarily while the filter-plant was undergoing repair (Lowell, Mass., 1902, Brewer, Poughkeepsie, N. Y., and Millinocket, Me.). Various public wells becoming infected through ground seams have caused epidemics of typhoid fever, as at Trenton, Newport and Mount Savage, Md.

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

THE VALUE OF HUMAN LIFE

Various attempts have been made to determine the exact financial loss occasioned by the invasion of an epidemic or a polluted water-supply. It is possible to estimate the approximate saving of life through safeguarding the public interests; the approximate number of lives saved by the installation of a water filtration system may be easy. But to put on the credit column of the ledger page for comparison with the debit of the filtration plant the actual value of the lives saved, with the dollars saved in wages of the deceased people, is an utter impossibility. All attempts to place an exact cash loss caused by any fatal calamity have and must result in failure. In estimating the loss from a fire the cost of rebuilding and probable loss from earning capacity during the period of construction can be roughly figured, but the other factors, inconvenience, effect on prestige, result of public attention, loss of unforeseen opportunities, etc., can not be surmised. Equivalent conditions affect the estimation of the value of human life and the cost of sickness. In estimating the financial loss during the illness of an individual or number of individuals the cash loss to that individual may be computed, but not the loss to his employer. Much less can there be calculated the wage loss occurring through death. It is obviously impossible to estimate how long a man's income will continue, to what extent it will fluctuate, of what value that income will be to himself and his dependents, and how much of that income will be inherited by others. Rochard says that the economic value of an individual "is what he has cost his family, the community or the state for his living, development and education." To accept such a standard would be to declare that Abraham Lincoln was worthless.

A man's value is not to be estimated by his income or bank account alone, but by his real influence, morally, mentally and physically on his family and the people at large. The man who spends much of his spare time at home and gives much comfort to his family is obviously of more value than he who does little for his wife and children except to pay the rent and grocery bills; he who influences his own or other peoples' children to improve in morality, industry and citizenship is greater than he who has little regard for such activity; the man who actually earns his money is of more value than he who inherits his sustenance, yet their wills may dispose of similar estates. These conditions are but a few of the many which must be considered when estimating the true value of a human life, and plainly show the absurdity of attempting to put on paper the loss caused by death. The human life is valued at $25 by Galton, $219 by Rochard, $776 (159 pounds) by Farr, $976 (200 pounds) by Chadwick, $2,000 by E. F. Smith and $5,000 by some others. French soldiers are rated at $1,200. The average price of slaves sold in America was about $1,000. Such estimates are obviously too low for any practical purpose. The legal value of life is almost entirely dependent on the force of the plea of the counsel.

Another error in estimating the human value is in the choice of incidental expenses. For instance, Wing, in attempting a concrete study of the cost of typhoid fever to Pittsburg, added into the expense account the extra cost of milk and ice used for the patients, neglecting to subtract the money saved by restricting the diet. Funeral expenses, $3,186 for 26 deaths, were included—an obvious mistake, because they are necessary expenses which must come at some time. Should it become necessary, as it unfortunately frequently is, to use concrete figures to convince lawmakers and the public of the benefit to be derived by protecting the public health, recourse must be had to the financial loss through the prevalence of sickness, including a list of the number of deaths, with a brief on the general loss to the public and private citizens occasioned by the mortality.

In reaching the estimate of the financial loss occasioned by sickness the sum total of the individual cases must be considered. In this there should be included only the value of the medical attendance, cost of nursing, extra servants, hospital expenses, medicines, special apparatus or appliances bought, extra ice and difference in cost of food supply, to which is added the loss of wages calculated up to the time when the patient attains his original vigor and wage-earning capacity. To this money loss, credited to those that recover, is appended the simple statement of the number of deaths, without attempting to express their loss in dollars. For a very rough working hypothesis of the financial loss, if this be required, the loss may be estimated as double the wages lost through illness and convalescence, with a minimum average of $3 a day, added to a bald statement of the number of lives sacrificed. Those who control means for the safeguarding of human life should use, if need be, for the value of life the personal standard placed on their own families. It is, therefore, very misleading to attempt to employ any set figure as the value of human life.

POLLUTION BY FACTORY WASTES

Manufacturing plants are not a danger from their sewage alone, but their liquid wastes when discharged into watercourses are undoubtedly a damage which needs correcting. Factory wastes are not only a menace to the individuals consuming the water, but are a detriment to other mills and are destructive to fish. By discharging offensive wastes into streams, ponds or lakes the manufacturer disobeys the clearly enunciated, universal law of water rights which commands that factories must allow the water leaving their mills to be as pure as when they receive it; the riparian manufacturing proprietor may use the water in any manner as long as he does not interfere with the purity of the stream or with the rights of others below him. Because of this factory pollution there has resulted much litigation; old established mills have been badly affected by the new factories up-stream; paper mills have been ruined and others forced to seek new quarters. In Rhode Island a bleachery obtained an injunction against a wool-washing concern, with the result that now the discharged water is subjected to settling basins, treated with sulphuric acid, the extracted grease collected in bags, pressed hot and made into dégras for finishing leather. The effluent is subsequently run through a sand filter. Woolen-mills and print-works have obtained similar injunctions against other wool-washing works up-stream, and many paper-mills have been rightfully sued.

Chlorinated lime from paper or cotton bleacheries when discharged into a stream grossly polluted by sewage will act as a partial purifier through its disinfectant effect, but the quantities added are in such excess of what is needed that a poisoning of the water results. The indications are that chlorinated lime can not serve as a coagulant in the manner of slacked lime, and will, therefore, not settle to the bottom of a river. Leighton asserts that acid coal mine wastes are, bacteriologically, a benefit in the Susquehanna River.

POLLUTION DESTROYS FISH

The scarcity of food fish is largely due to the pollution of the streams. Some coarse fish apparently thrive near a sewer's mouth, but may be rapidly killed by a discharge of sulphuric acid or other waste. The destruction of fish by sewage-laden water is due to bacterial contamination, to various salts or to gases of decomposition, ammonia and sulphuretted hydrogen. Marsh is of the opinion that the exhaustion of the dissolved oxygen causes the fish mortality. The Passaic shad industry was utterly destroyed by pollution in the river. In many cases fish are destroyed by factory wastes. Dead fish were found in countless numbers after arsenated water was discharged once from a dye works. Sulphuretted hydrogen from starch works, lime from bleacheries, gluten from glucose works, coal-mine and culm bank washeries and decomposing animal matter are all causing enormous destruction of fish. Sawdust and wood pulp destroy trout and bass. The wastes from woodpulp mills, oil wells and gas factories make fish life impossible (Leighton, Marsh, Sweeney). The stocking of streams by the planting of young fry is frequently a failure because of water pollution. The fresh content of a stream may usually be regarded as a relative indication of objectional pollution, as the salt content is considered as a relative indicator of sewage.

The sewage and factory pollution of the streams, with the noxious odors and surface impurities, and with the resulting absence of the smaller fish, is an important factor in the scarcity of game and other birds on the shores. The same causes make it impossible for people to live near some streams or to water live stock therefrom. Realty values decrease markedly along streams which become polluted. Land along the Passaic River that commanded values of $500 to $800 an acre for farming a few years ago possessed no value at all in 1902.

Since factory pollution is frequent and easily visible, its presence may best be detected by those who are accustomed to visit the manufacturing plants. Factory inspection is a necessary requirement in every state and city, but it seems advisable to place it under the guidance and control of a state department of health; at least, the inspectors should be required to submit sanitary reports to the health bureaus. It is most philanthropic for the factory inspectors to determine the presence of any employés under the legal working age, but more benefit would be derived if more attention were given to the sanitary and health conditions affecting the individuals. It should not only be determined that proper toilet facilities were provided for the employés, but that these toilets are properly located and maintained, and are not a menace. Too many factory toilets are built directly over streams and conducted in such a way that flies may readily carry germs to food-supplies. To determine the age of a child in a factory may save a single life, but to determine where that child has been forced to deposit his discharges may save a hundred. It is the saving of the masses that must be perfected.

No untreated offensive factory waste should be permitted to be discharged into watercourses. Such wastes, as dyes, chemicals, acids and bleaching powders, should be subjected to appropriate chemical precipitants or to coagulants that will render the effluent from settling-basins clear, colorless and free from contamination. For many wastes, aluminum sulphate is the safest and most effective coagulant, but for others ferrous sulphate or slaked lime is preferable. Coke filters possess an absorptive power for many coloring matters (Dunbar). In some cases, as with brewery wastes, it may be more satisfactory to include the factory wastes with municipal sewage rather than to attempt to treat them separately. If possible the wastes should be converted into industrial profit, as is being attempted with sulphite pulp waste.

EFFICACY OF FILTRATION

The influence exerted by the establishment of sewerage and of water filtration is clearly shown by the following table of the typhoid mortality:

Rate per 100,000 Population.	Before Sewerage.	After Sewerage.	After Filtration.
Boston	174	60	20
Lawrence	96	18	2.1
London	90	50	14
Berlin	92	50	5
Breslau	92	40	9
Munich	254	27	9
13 Mass. Cities, average.....	79.4	38.3	

In other words, water filtration caused a reduction in the typhoid mortality rate of 98 per cent. at Lawrence, 90 per cent. at Ashland, Wis., 80 per cent. at Binghamton, N. Y., 76 per cent. at Philadelphia, 75 per cent. at Watertown, 66 per cent. at Boston and 60 per cent. at Albany.

The bacterial efficiency of sand filters shows that practical application does not fall much below experimental results. In the experimental sand filters at Lawrence 99.48 per cent. of the bacteria were removed, and at the Pittsburg experimental plant 99 per cent. In practice the efficiency of the Providence filters is 99.68 per cent.; Philadelphia, 99.59 per cent.; Rensselaer, N. Y., 99.48 per cent.; York, Pa., 99.57 per cent.; Lawrence, 99 per cent.; Loraine, Ohio, 98 per cent.; Elmira, 98.43 per cent., and Norfolk, 95.99 per cent.

Turbidity is another objectionable condition removed by water purification. It is not only an esthetic objection, but in various industrial establishments an actual menace, and frequently necessitates the installation of private filters. These filters are not sufficient to remove all turbidity and coloration. The removal of fine mineral turbidity, such as comes from clay and culm, can not be accomplished by slow sand filtration, but requires a coagulant.

The turbidity from culm comes principally from the washing of the culm banks in the recovery of buckwheat and rice coal.

Rural contamination of streams should receive more consideration than has been accorded to it; and means must be adopted to check the damage resulting from privies which are placed over streams or on the river banks, and from remote factories discharging into the watercourses. Camps, be they for military, for pleasure, for workman or gypsies, should be so located that the privies are situated far from all streams and far from the camps themselves. It is preferable for the toilet to be erected on the summit of a hill, provided there be no pump or well immediately below. Since it is possible for the direction of flow of ground water to be in the opposite direction to that of surface water, as toward a hill summit, in locating wells and cesspools the position of the near-by large watercourses must be considered. Ground water tends to flow toward the larger streams or rivers, without being necessarily influenced by intervening hills. The epidemic at Ithaca probably resulted from a gang of Italian railroad workmen establishing their camp along the water supply. These camps should have definite latrines erected, the location of which should be occasionally changed.

Some writers persist in saying that there is no objection to a farmer emptying sewage into a stream, and Lake adds the provision, "if the stream is not used for domestic supply." A stream not used for a domestic supply is a rarity; except in few unsettled districts, all streams had better be regarded as domestic supplies. To empty sewage into a watercourse is probably more dangerous than the use of the old-fashioned privy, except where the privy is in immediate proximity to a well.

Stream pollution is far more dangerous than the use of a properly situated, properly constructed and protected privy. Sanitary engineers accept the theorem that it is the time consumed and not the dilution or rapidity and turbulence of a river that is most responsible for the bacterial purification of streams. If typhoid germs are discharged into a stream which flows at a rate of five miles an hour, which is a comparatively quiet stream, accepting Russell's results that the germs will die in five days, those germs could be carried 600 miles, surely far enough to reach some domestic supply. Hence it may be concluded that any pollution, however remote, is apt to affect some consumer, unless it occurs near the sea.

To assist in the purification of watercourses, physicians should be required to disinfect all discharges from typhoid and tuberculous patients. Physicians should be more prompt in reporting infectious cases, being required by law and encouraged by printed postals. They should report cases of insanitation coming under their notice. Local health officers and factory inspectors should inspect temporary camps of workmen and pleasure seekers, and should inspect and report to a central authority all examples of stream pollution from towns, houses and factories which occur within their precincts, as well as any gross polluted appearance of the watercourses. The finding of dead fish in a stream, being indicative of some kind of pollution, should lead to an inspection, and the saving of fish should be an object. Before establishing a filtration system cities should determine the feasibility of obtaining water from an unpolluted locality which can be kept under control. Watersheds should be patroled. A good man on the alert can patrol a large district, getting his information through various ways and personally inspecting all suspicious localities frequently.

By securing legal enactment and arousing public sympathy through the use of statistical and experimental evidence, with the use of uniform standards to reppresent financial results, the work of the sanitary corps is strengthened. Their work becomes more efficient by obtaining notices of legal or hygienic encroachments through such channels as information can come, and eternal vigilance on the part of the few brings success and life to the many.

5038 Pine Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. EVANS AND WOOD

Dr. W. K. Jacques, Chicago: I drink Lake Michigan water, and I think that every one who is thus afflicted ought to be thankful to Dr. Evans for this paper and also for the water commission which was started under his influence and instigation. If it keeps on as it has begun, the data which will soon be collected will be of the greatest value to those who are obliged to depend for their drinking water and domestic water supply on Lake Michigan and the tributary lakes. It is strange that the very people most interested are the people who do not care to take part in this sort of thing. As an illustration, I have a summer home across the lake in a small city, and when I first went there the people of that town were depending on the disposal of excreta in privies, as in ordinary country places. Within five years a sewer has been opened and extended down into a little river which passes through the center of the city. The water supply is taken in along this river from Lake Michigan. Since the sewer has been emptied into the river typhoid has been a veritable scourge in that town. Last winter it was decided that something must be wrong with the intake; a diver investigated and found twenty-three places where the intake was defective and the river water was going in through the intake. That is, he reported twenty-three places; and that is all they had money enough to repair.

Now, the City of Chicago sends to this city over a hundred thousand people every summer, a large proportion of whom are young and especially susceptible to typhoid infection. It would pay Chicago to extend that water intake; but we, of course, are unable to do it; and this state has withdrawn from this commission; so that the very state that needs it most will get the least benefit from the commission. The proper disposal of this sewage before it is even emptied into the river and the extension of that intake a mile out into the lake are what should be required.

Dr. L. H. Montgomery, Chicago: I was pleased to hear Dr. Evans in his paper state that, in his opinion, the federal government should have control or supervision over the chain of our northern lakes, having reference, of course, to the pollution of the water. I do not know whether he intended to intimate that the general government should have control of the rivers discharging their waters into those lakes. I would favor federal control of streams and rivers as well, as many, if indeed not all of these larger rivers serve as open sewers throughout the United States. We seldom hear of any one being prosecuted for pollution of rivers; factories are located on rivers and lakes; discharges are emptied there by the employees; and while many of the commonwealths have laws prohibiting pollution of springs, lakes, rivers and other sources of fresh water for domiciliary purposes, yet the legislatures do not make the financial appropriations for the observance of such laws and the punishment of violators thereof. This pollution goes on year after year, then somebody awakens, and, as Dr. Jacques says, money is appropriated which goes so far and no farther, partly removing the trouble while the menace to health still goes on in a degree. There is negligence, and it is often, I believe, from lack of appropriations that state authorities do not go ahead and carry out the law. I believe that the national government should have control over all these matters connected with our great rivers and lakes throughout the country.

Dr. W. Forrest Dutton, Walker's Mills, Pa.: I believe that the members of this Section who were in Chicago last year remember the courtesy shown us by the City of Chicago when, through the hospitality of Dr. Evans, we were shown the wonderful mechanism of Chicago's water supply. To my mind, it is one of the most wonderful pieces of sanitary work that I have ever seen; and I believe that the municipality of Chicago does not really appreciate the hard work that Dr. Evans has put into its department of health. I believe that if Dr. Evans is maintained at the head of the department of health in the City of Chicago, in a very few years he will make it one of the cleanest cities in the world; whereas, some few years ago, it was referred to as one of the dirtiest. Coming a little closer home, to the City of Pittsburg, since the installation of its filtration plant, the rate of typhoid mortality has been reduced from 200 per 100,000 to about 15 per 100,000. It is impossible to filter the steel mill chemicals from the river water. These so irritate the intestinal tract that it readily becomes a point of attack for the typhoid bacillus. If the large municipalities throughout the United States had such officials as Dr. Evans of Chicago, Dr. Hurty of Indianapolis, Dr. Bracken of St. Paul, and the eminent sanitarian, Dr. Egbert of Philadelphia, we should have a much better record to show to our brethren abroad.

Dr. Seneca Egbert, Philadelphia, Pa.: I would like to take issue with Dr. Montgomery as to the government taking charge of all rivers and streams. I believe that the government should take charge of the great chain of lakes, but we are demonstrating in Pennsylvania that we do not need the United States government's help. With a fair appropriation from the state legislature, and men who have nerve enough to do the work, it can be done by the states. I am enough of a states' rights' man to believe in that sort of thing. It was said not long ago that the Pennsylvania State Commissioner of Health had cleaned up over 4,000 sources of pollution along the Schuylkill that supplies most of Philadelphia with water. Those of us who live in Pennsylvania all know that a tremendous amount of work toward the protection of the streams can be done—and has been done—by a man who has the power of the state back of him, a good, thorough appropriation, and then enough nerve to do the work. More than that, I think Philadelphians as well as Pittsburgers have appreciated the benefits of the improvement of the water supply. In my own ward, one of my near neighbors, a practising colleague, a few years ago had 30 cases of typhoid fever in a year; he now has 3. We are practically eliminating typhoid from Philadelphia, which used to be notable for its excess of this disease.

There is another phase of the question: Since we have learned so much in the last two or three years about typhoid bacilli-carriers, it seems to me that the importance of this question of the non-pollution of streams is greater than it ever was before. We know now that people traveling from place to place can still carry the infection of a typhoid attack of months or years before to those places; and if the drainage from any privy or cesspool can get into the water supply, they may become sources of typhoid infection to large numbers of people. Many and many a small town, and almost all the smaller hamlets, have no common water-supply or any sewer system, and the people rely on the old-fashioned well and the old-fashioned privy vaults. In such places the danger of infection must be occasionally present and we cannot give too much attention to this problem.

Dr. Marshall Langton Price, Baltimore: There is a single point in Dr. Wood's paper that I want to touch on; that is the estimate of the economic loss caused by the death of a human being. It is admitted, of course, that any computation is unsatisfactory, and often inaccurate; but whether we have an accurate or inaccurate standard, we ought to agree on some standard of computation. I recently recommended for that purpose what I call the life-capital method. That is, computing an indivdual's earnings up to the time he becomes economically disqualified, or up to the time of his death, we can calculate the loss in life capital by using any of the standard life-tables. From these we can calculate the average expectancy of life at the time the individual dies of any disease such as typhoid. If a man earns $2 a day from his eighteenth to his thirtieth year, he will accumulate $10,000 life-capital: that is, he has lived a $10,000 life. Of course, if those earnings are interrupted by death or disease, he has evidently lost part of his life-capital—that which under the life-capital method he would have earned if he had remained alive to his thirtieth year. You have to give definite limits to the working period; but it strikes me that it is about the best standard which we can devise at the present time as a unit, and one least liable to misconstruction. In regard to typhoid being a rural disease, that fact was first pointed out by a civilian, Colonel Waring. The subject was later exhaustively described by Dr. Fulton in a careful comparison of rural and urban typhoid fever; and he found, in his studies, that the rural mortality was very considerably higher, I think almost 50 per cent.

Dr. John S. Fulton, Baltimore, Md.: I classified more than 300 cities according to their populations, and found that the five largest cities in the United States had the lowest typhoid mortality, averaging about 25 per 100,000. The average for these five cities, at this time, would be found lower. From this minimum of 25 per 100,000 the mortality was found to increase as the scale of population diminished, until the heaviest typhoid mortality was reached under truly rural conditions, i. e., where only about 10 per cent. of the people live in towns. Rural populations suffered a typhoid mortality of about 65 per 100,000. Pittsburg caused an irregularity in this descending scale of mortality, the monstrous mortality of this city raising the average for all the cities of that class to about 45 per 100,000. While the article to which Dr. Price refers may have been the first in which convincing figures were shown, it was not far ahead of Dr. Egbert's article in which the same conclusion was reached. Long before either of us looked into the statistics, Colonel Waring said, in the introduction to his work on "Sewerage," that typhoid fever is a rural disease, and its progress is in general from the country to the city, rather than from the city to the country. It was a layman, therefore, and not a physician, who first called attention to the error, so prevalent among medical writers, of discussing typhoid fever as one of the chief scourges of cities.

Dr. F. W. Sell, Rahway, N. J.: I want to speak a word for New Jersey, and to say that we have now, I think, taken an advanced position, alongside of Pennsylvania, Massachusetts, and New York, in the way that our state board of health is supervising the disposal of the sewage of towns on our watersheds. I think that there are no less than 53 disposal plants now under the supervision of our state board either on the shore or on inland watersheds. Individual cities have tried to oppose the putting in of these plants because of lack of education. They do not seem to realize the necessity of it; but the time will come, I feel sure, when they will all fall in line; and one very great sign of the times, I consider, is shown in the cooperation of the states of New York, Pennsylvania and New Jersey along the Delaware, in a similar manner to that of the cities and states which Dr. Evans has described.

Dr. J. H. White, New Orleans: I do not believe that national control should be extended any further than that point at which the people with practical unanimity shall propose the surrender of their authority to the nation and admit that the job is too big for them. The point where national control should come in (and this is what Dr. Evans claims) is on waters that are interstate, on waters which involve, especially, as the lakes do, not only interstate, but international issues, and in similar cases. I am a representative of the national health service, and I want to make it plain that we are not trying to gobble what does not belong to us.

Dr. W. A. Evans, Chicago: The situation in Chicago is this: Twenty-four miles north is Waukegan, a city of 30,000. The intervening distance is solidly filled in with smaller towns. The sewage of these, nearly always raw, is poured into the lake. The drinking-water is taken from the lake at points always less than one mile from shore. No intake is more than two miles from the nearest sewer outfall and some are much nearer. The water is not filtered. Then comes Chicago's twenty-five miles of lake front. In this sweep no sewage enters the lake except through the Calumet River, located two miles from the Indiana line. In it there are six water intakes; one, about two miles from Chicago's north line, is located close in shore, but is supplied with a filter; the others are from two to four miles out; they do not have filters. Joining us on the south are Hammond, East Chicago, Indiana Harbor, Whiting and Gary, having a combined population of about 100,000. These towns put one-half their sewage into the Calumet River and the other half directly into the lake. The Calumet River receives the sewage of about 200,000 people; 50,000 in Indiana and 150,000 in Chicago and Cook county outside of Chicago. None of this sewage flows over ten miles in the river and the bulk of it flows less than three miles in the river. About half the Calumet River is in Indiana and half in Illinois. Its mouth is in Illinois two miles from Indiana. The Indiana towns, except Gary, have water intakes within a few hundred feet of shore and a few hundred feet of sewer outfalls and are without filters. The sewage is raw. From the Calumet River to the nearest Chicago intake is about four miles. From the Calumet River to the farthest Indiana intake, except Gary, is about five miles.

There are no constant water or wind currents in Lake Michigan. The current is with the wind. A lake flow of five miles is not sufficient to purify a large volume of sewage. When a strong north wind blows every town is polluted by the town north of it. And the Calumet River, carrying Chicago sewage, pollutes the Indiana towns. When the wind is from the southeast the Indiana sewage pollutes the Chicago water and every town up to Waukegan is polluted by the towns south of it.

Whose problem is the Calumet—half in Indiana, half in Illinois—discharging in Illinois two miles from the line, and with a lake flow into Indiana waters whenever the wind is from the west or north? Can any government handle a problem like this except the national government? Are not lines of demarkation between states theories, while a stream of sewage pollution from the Hammond sewer to the Chicago intake is an actual condition? If the national government has not now a way, is it not up to them to find a way?

Then there is the matter of dumping dredgings into Lake Michigan near water intakes. Much of this dumping is done under contract with the War Department. In Chicago waters most of this is clay and it is dumped in water sixteen feet deep. Storms stir Lake Michigan to a depth of fifty feet at times. Consequently our drinking-water is often muddy after a storm. We are insisting that this dumping be done behind breakwaters or else in water over fifty feet deep. The position taken by the chief of engineers is that the government has exclusive control of dumping, the city has no authority, but that the government has no right to be swayed by any consideration of health. To this I would say that if the government officials finally conclude they have now no way, it is up to them speedily to find a way.

I wish to mention another point before concluding. I know of a town near Chicago which has located its intakes with relation to its sewer outfalls on the basis of a continuous lake flow in one direction, and not far away is another town which has its water intakes located on the basis of a flow in the opposite direction. Each is wrong.

Dr. Harold B. Wood, Philadelphia: To her honor, include New Jersey with New Hampshire. These are the two states having the lowest typhoid mortality rate. In Pennsylvania, Dr. Dixon, that he may best overcome the rural typhoid mortality, is having sanitary surveys made of all streams. The work at present is being done in the western part of the state, having accomplished a sanitary survey of every tributary of probably three-fourths of the Allegheny river. In regard to the utilization of privies: Sanitarians have been working for some time to abolish privies, warning the people, but advising them of no methods for a proper sewage disposal in the country places or for factories situated along streams. One town in the South, of probably five or six hundred inhabitants, uses, I am told, about forty privies situated along a river bank overhanging the stream. The lack of danger from some privies (that is, excluding the danger from fly contamination) where they cannot pollute water supplies, can be well illustrated by the case of Media, Pa. Recently I talked with a physician who said that in the last ten years there had been not five cases of typhoid fever in Media, a city of about 4,000 inhabitants. Dug privy wells is the only sewage disposal. The water is entirely pumped from a nearby stream, an excellent water, practically under control. One of the contentions to be met in Philadelphia is the impatience of the people. Recently there has been a small typhoid outbreak there in the northern part of the city, that part which has just been supplied with filtered water. Immediately the newspapers and the general public concluded that there was an inefficiency in the slow-sand filters. There is no doubt that the infection came *almost entirely through* food-supplies, flies and importation. In this outbreak the milk supply could be excluded. Some of the people in Philadelphia doubt the utility of the filters on account of their not excluding all turbidity, never having been instructed by the newspapers, or in any other way, that the finest turbidity cannot be removed by slow-sand filtration. Of course, it must be admitted that it is extremely difficult to detect the typhoid bacillus in water. While most experimenters adopt the Drigalshi-Conradi method, Dr. Bergey employs a test founded on the fermentative ability of the bacteria; and Dr. Rives, Pennsylvania's state bacteriologist, depends on his colorimetric test. A sanitary inspection is of as much value and dependence as a laboratory analysis of a water. In view of doubts expressed, the evidence is conclusive that water is contaminated and often transmits disease.

Clinical Notes

SYMPTOMS FOLLOWING THE CUTANEOUS TUBERCULIN TEST, SUGGESTIVE OF A SPECIFIC GENERAL REACTION

F. BUCKMASTER, M. D.
EFFINGHAM, ILL.

A few months ago when Dr. C. von Pirquet made known to the medical world his tuberculin skin test much was hoped from it in a diagnostic way, and, indeed, much was promised. Simplicity of detail, practical reliability, and freedom from specific general and focal symptoms were claimed for it. There can be no argument as to the first claim made for this test, but much has been said against its reliability as a diagnostic means in tuberculosis. Regardless of what we had expected of it, or of what had been claimed for it in a diagnostic way by Dr. von Pirquet, it has never been determined definitely as yet just what its true diagnostic reliability is, or will prove to be, in the various forms of tuberculosis.

However, opinions on its diagnostic value may have been at variance, it seems to have been generally conceded by those who have used it that it was free from specific general and focal reactions in the presence of tuberculous disease. Regarding these reactions Dr. C. von Pirquet[1] himself has the following to say:

> My cutaneous method has the advantage over the injection of tuberculin, that it does not produce any general symptoms. . . . . It is, however, not as sensitive as the *Stichreaction*, and does not produce inflammatory phenomena of the tuberculous foci, which after Koch's injection can be utilized diagnostically."

These views as expressed by von Pirquet seem to have been looked on by all as being true. I wish at this time, however, to report a case exhibiting symptoms, unmistakably those of a specific general reaction, following this skin test. The history follows:

History.—Miss G. B., aged 27, was seen June 23, 1909. Father died at age of 50, from hepatic abscess, complicated by some form of chronic pleural and pulmonary diseases, likely tuberculosis. Mother died at 61 from heart disease. Two brothers alive; one is said to have Bright's disease. One brother died at 21 from tuberculosis, following an attack of influenza. Four sisters alive and well; three dead, one at 16 from heart disease; one at 17 and one at 19 from tuberculosis. Patient does light housework at home when able. Was well as a child, except for pneumonia at 5, of moderate severity, from which she made a good recovery. At 7 she was in bed six or seven weeks with an attack of typhoid, making a good recovery after about three or four months. Had febrile attacks at 14, and at 24, which was diagnosed as typhoid, but she was never totally confined to bed during their course, but in each instance was "up and down" for two or three weeks. Permanent recoveries seemed to her to be good. Had an acute bronchitis during the past spring, having some fever and cough for a week or two, both finally leaving her, but she says she has not been so well since that sickness, and that she has had soreness, and at times a weak feeling in the chest. Has much pain and soreness in the right upper abdomen, at times, and says stomach feels better after eating; says she has a hungry feeling or pain, which causes her to eat often between meals, and occasionally during the night. No vomiting, except a few years ago when she had severe acute attacks of pain. Menstruation has always been regular, beginning at 12, quite free, of four or five days' duration; has pain and cramps, and is usually in bed a day or more. The last period appeared the middle of June. Has had some leucorrhea this spring.

---

[1] The Journal A. M. A., Feb. 27, 1909, lii, 675.

Present Illness.—Began six years ago with a right abdominal pain, cramp-like, and intermittent, which kept her in bed for about a week. Says the right side of the abdomen was very sore at the time. Says she gradually recovered, but has had light attacks of pain and soreness in the same region every few days, which she thinks would have amounted to one week in each month, but says the trouble was not connected with the regular times for the periods. Four years ago she was in bed for two weeks with another severe acute attack, apparently of the same trouble. She vomited during this and the first acute attack. Recovery from this attack was very imperfect, and she has almost never been free from her abdominal pain and soreness since, but never in bed with it again, though she has worked some at times. Her trouble has gradually grown worse for the past four years, until about three weeks ago, when she says she felt something give way in her, as it were, and this was followed in about two hours by the discharge of about a pint of pus by the rectum. She continued to pass more pus by the rectum at intervals, for the next five days, when it totally ceased. While passing this pus she had freedeom from pain, but when the discharge ceased the pain and soreness again became prominent. No cough and no night sweat. Patient has been "up and down," and has been without fever during the two weeks that Dr. Broadway has treated her.

Examination.—The patient looks weak and tired; weighs 97 pounds; skin is dark, pupillary reaction is slow, tongue is coated, has no goiter. Patient has a well-formed and a well-filled-out chest, and expansion is good. Lungs negative, except perhaps for the slightest harshness in the breath sounds in the outer half of the upper third of the anterior surface of the right lung. Heart negative and pulse 74. Abdomen, to inspection and percussion, appears normal. Liver slightly enlarged. Spleen normal in size and position. The right upper quadrant is very rigid and very tender, with the tenderness seeming to center over the gall-bladder and the duodenum, diffusing out over the pylorus, and downward toward the appendix, though in the immediate appendiceal region there is no rigidity, but there is much tenderness deep in at McBurney's point, showing the unmistakable appendiceal lesion, indicated by her history.

The left side in total, and the right lower quadrant except the appendix shows no tenderness, and no rigidity, except for a left rectus rigidity for about two or three inches, opposite the umbilicus. No tenderness here though. No masses can be made out. No renal tenderness, or displacement, nor can other visceral displacement be made out. Bimanual by rectum shows nothing, but apparently normal conditions. Temperature and pulse during the afternoon remained normal. Bowels have been moving two to three times a day, without diarrheal tendency. The von Pirquet test was made about 1 p. m., the upper and lower points on her arm being inoculated. Patient was left in bed on a very light diet, and with ice-bag on abdomen.

The next morning the patient complained that she was really sick, felt flushed and full headed, nauseated, with scant vomiting, and had an increase in her abdominal soreness and much more pain, and at 9 her temperature was 101.6 and pulse 100. During the day her temperature reached 102, and the pulse a little above 100, and she was "sick," as she expressed it, all day, could eat nothing, and had some headache, though this has been a very infrequent symptom with her. By 8 in the evening her temperature had dropped to 100 and the pulse to 86, and she felt much better in every way, the nausea and the oppressive feeling in her chest clearing up. During this day and the next, considerable harshness in breathing and a little dulness on percussion existed in the part of the right lung where I had the day before heard a little harsh breathing, but no râles were heard.

On the next morning her temperature and pulse were normal, and have remained so for the past three days, and her soreness and pain have entirely cleared up from the rest and ice-bag, and she has had no nausea nor other of the disagreeable symptoms so prominent the next day after the skin test was made. The local reaction on the arm, beginning to show on the same day the fever and other symptoms showed themselves, became very bright.

The total sample of urine for twenty-four hours was 52 ounces, with a specific gravity of 1.008, but was negative to all further tests. No tubercle bacilli in the little bit of sputum once collected, and an analysis of the stomach contents made on two successive mornings showed each time four ounces withdrawn, of a smooth even consistence, showing that it was being well digested; no free hydrochloric acid and no organic acids. One examination showed the combined acids at 65 points Toepfer, while the next showed 60.

Operation (June 29, 1909).—Chronic adhesive appendicitis was found, the appendix reaching up practically to the right kidney. The adhesions were attached high up to the mesentery of the ascending colon and were drawn very tight, evidently causing the pain. Stomach, duodenum, bile system and pancreas were negative. Pain left the patient and all soreness cleared up shortly after operation and she went home the eighteenth day. There were no appearances of tuberculosis in the abdomen. Since the patient went home she has taken fats freely and sleeps out in a tent and is doing well.

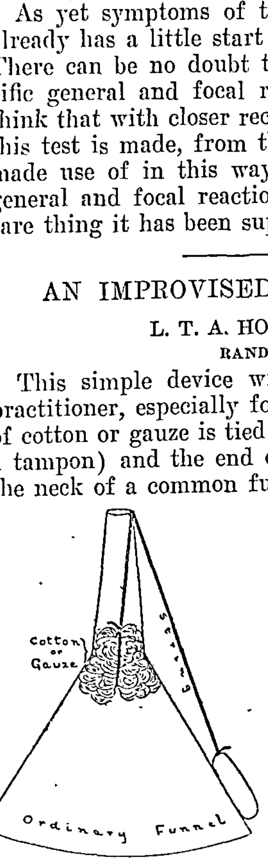
I noticed in THE JOURNAL[1] a report by Dr. Rayevsky of two similar results. One of his specific general reactions was much more marked than occurred in my one case. Otherwise the time of appearance of the symptoms and their nature tallied very closely in all three cases. No hoarseness developed in my case, as the throat and larynx were free from involvement.

As yet symptoms of tuberculous involvement, which already has a little start in the right lung, are lacking. There can be no doubt that this patient showed a specific general and focal reaction, and I am inclined to think that with closer records kept on patients on whom this test is made, from the large dose of the tuberculin made use of in this way, we shall find that a specific general and focal reaction will be found not to be the rare thing it has been supposed to be in the past.

AN IMPROVISED ANESTHESIA CONE

L. T. A. HOTTENDORF, M.D.
RANDOLPH, UTAH

This simple device will appeal to many a country practitioner, especially for obstetric work. A small wad of cotton or gauze is tied up with a piece of string (like a tampon) and the end of the string is passed through the neck of a common funnel and tied in place outside. The anesthetic is dropped on the cotton as required. The amount of cotton or gauze should vary, depending on whether it is desired to use the anesthetic by the drop method or to saturate the pad. The patient can hold the cone herself, and, therefore, there is no possibility of giving too much anesthetic. I have found this simple arrangement very satisfactory in a great number of cases.



---

ABNORMALLY LONG VERMIFORM APPENDIX *

H. P. COLE, M.D., and GILMAN J. WINTHROP, M.D.
MOBILE, ALA.

The average length of the appendix, as stated by different authors, is from 8 to 11.5 cm (3 to 4½ in.), with a mean of 9.2 cm. (Kelly, Ribbert and Berry place it at about 8.3 cm., 3¼ in.), or between 3 and 3½ inches. Abnormally long appendices have been noted by J. D. Blake (24 cm.—9⅓ in.), Lafforge (24 cm.—9⅓ in.), Luschka (23 cm.—9 in.) and Lenzmann (22 cm.—8⅔ in.). Below we report a case in which we removed an appendix 20.9 cm. (8¼ in.) in length, about two and one-half times the normal length.

History.—The patient was a mulatto woman, aged 31 years, having what we diagnosed clinically as a myoma of the uterus and an ovarian cyst (left).

Operation.—On Dec. 3, 1908, under ether anesthesia, a pedunculated myoma 13.5 by 13 by 13 cm. (5 1/5 by 5 by 5 in.) was removed by tying and cutting the pedicle. A large ovarian cyst, together with the Fallopian tube, was removed from the left broad ligament. A small cyst was removed from the right ovary. On looking for the appendix almost complete absence of the mesoappendix was noted. The appendix lay in the second most frequent position ascending vertically behind the cecum and first portion of the colon, and partially attached to the dorsal wall of the large intestine. The tip extended to the level of the upper pole of the kidney. Considerable difficulty being experienced in freeing the appendix, its peritoneal coat was incised at the cecal junction and the appendix then stripped and dissected free from this covering. The stump was ligated and inverted into the cecum by the usual purse-string method. The uterus was then suspended and the abdomen closed without drainage. The patient made an uneventful recovery and left the hospital twelve days after the operation.

This appendix had apparently given no symptoms. It was probably drawn into the ascending position by the formation of early adhesions between the appendix and the other organs lying posterior to the cecum at the time of its descent, as suggested by Kelly. Removal was undertaken because of the more frequent occurrence of inflammation in appendices lying in this position.

TECHNIC IN TRANSFUSION

HERMANN B. GESSNER, M.D.
Professor in the Miles Laboratory of Operative Surgery, Tulane University of Louisiana
NEW ORLEANS

In experimental work in the laboratory, in which I have had the assistance of Dr. W. Lassiter, we have found the use of the fine tenacula of the Elsberg outfit advantageous in doing transfusion experiments on the lower animals with the Crile tube. The tenaculum is thrust through the Crile tube, hooks the artery by the circumference, and draws it through more quickly and with less traumatism than when sutures are used for the purpose or the artery is pushed through. The artery once drawn through, a second tenaculum suffices to cuff the extremity over the Crile tube. Here the cuff may be secured with a ligature over one of the grooves or, if desired, it can be held in place with the two tenacula while with two more the recipient vessel is drawn over the cuffed donor vessel and a single ligature used to hold both over the tube.

The advantages are ease of performance, a minimum of traumatism, and economy of time.

ACUTE MILIARY TUBERCULOSIS FOLLOWING RENAL TUBERCULOSIS, SECONDARY TO OLD HEALED BILATERAL APICAL TUBERCULOSIS

PAUL H. RINGER, A.B., M.D.
ASHEVILLE, N. C.

The following case may be of interest to many as being to a great degree illustrative of the relations of cause and effect in the mobilization of tubercle bacilli after an apparent cure has been effected. In the case reported here no knowledge of the primary disease was obtained until the autopsy, the patient having died from general dissemination. A point of special interest is the intermediate route chosen by the tubercle bacilli, and their temporary halting place in the right kidney before spreading to the body at large.

Patient.—I was called on July 19, 1909, to see Mr. J. C., aged 28, a farmer from Kentucky, who had been in Asheville three weeks. Data were obtained from his wife.

History.—Mother and several brothers died of pulmonary tuberculosis. Patient well as a child; no past illnesses; was an athlete at college. About a year before this illness he had had "attacks" consisting of severe pain in the region of the bladder. These attacks came on after he had worked very hard building a house. The pain caused vomiting. These attacks recurred several times, and finally stopped. About six months before the present illness he had "stomach trouble" (nature very obscure), and his home physiciain said he had too much acid in the gastric juice; this was counteracted by an alkali. Three months before the present illness the patient began to run an irregular temperature and to lose weight and strength. For the past two months the temperature had been constant, ranging from 99 to 102. *At no time* had there been actual cough; there had been transient expectoration ascribed to "catarrh." The patient was examined in April, 1909, and was told that his lungs were weak but that the physician did not think it was tuberculosis. It was understood from what could be elicited from his wife that a Moro cutaneous tuberculin test was given—result not positive. The patient had been kept in bed for a month at home and then sent to Asheville. While here he was constantly in bed, growing steadily worse. His bowels were somewhat loose; he was said to be voiding a normal amount of urine.

Examination (July 19).—Patient poorly nourished, sallow and pale; dorsal decubitus; expression anxious. Evidently much loss of weight. Pupils equal, reacting both to light and to accommodation, though somewhat sluggishly. Tongue heavily coated. Throat apparently normal.

Chest: Note over all normal save for possible hyperresonance over the upper lobes. Breath-sounds normal over all. A few subcrepitant râles heard on deep breathing and on coughing in first right and left intercostal spaces. Also a few râles on left side in anterior and mid-axillary lines down to about the eighth rib. No adventitious sounds behind.

Abdomen: Tender over all. Liver, spleen and gall bladder not palpable. Some tympanites; no rose-spots. In hypogastric region there was a large tumor half the size of an adult head, sharply defined, smooth, tense, flat on percussion. It was in the region of the bladder and very tender to pressure. Patient voided about 12 ounces of urine on request. This was examined and found to be acid, sp. gr. 1,016, trace of albumin, moderate amount of pus, no other abnormality. Patient semidelirious for past three days—cerebration slow. Tried to get out of bed.

Course of Disease.—Owing to the inaccessibility of the patient's house and to lack of proper facilities for caring for him, he was brought to the Asheville Mission Hospital on the morning of July 20. During the night of the 19th he was given morphin gr. ⅛, which kept him fairly quiet. The next morning, July 20, he drove three miles and was admitted to the hospital at 11:45 a. m. suffering from a hard chill. At 1 p. m., the abdominal tumor persisting, and having seemingly increased in size, he was catheterized and 53 ounces of urine withdrawn, the tumor promptly disappearing. He was catheterized again at 9:30 p. m. the same evening and the large amount of urine withdrawn (84 ounces). The patient was given sulphonethylmethanum (trional) gr. 10 and passed a restless night semidelirious, trying to get out of bed and fancying that he saw many people around him. He was again catheterized at 2:30 p. m. on July 21 and 70 ounces withdrawn. I then called Dr. Charles L. Minor of Asheville in consultation. The patient was semi-delirious, quite dyspneic, not cyanotic, abdomen slightly distended, signs in chest as stated above. Dr. Minor and myself made a tentative diagnosis of acute general miliary tuberculosis, based on the following points: Probability of tuberculosis from the history; continued temperature for two months; marked cerebral involvement; abdominal symptoms; decided dyspnea with but insignificant chest findings; rapidity of pulse (120). An Arneth blood picture was made, *giving the following result:*

---

* Read before the Medical Society of Mobile County, Ala., Jan. 29, 1909.

I.	II.	III.	IV.	V.	Index.	
29.	42.	24.	3.	2.	83.	(High.)

Leucocyte count, 16,000.

Dr. W. L. Dunn of Asheville also saw the patient, agreed with our diagnosis and did a Widal reaction which was wholly negative in a dilution 1:30.

Patient was again catheterized at midnight on July 21 and 38 ounces withdrawn. Bowels being constipated, 2 drams of a saturated solution of magnesium sulphate were ordered every hour until bowels moved. Other treatment was simply supportive, strychnin and digitalis being given. At night the patient was given morphin, gr. ⅛, which kept him fairly quiet. July 22 patient catheterized three times—total of 64 ounces withdrawn. July 23 the patient had ten involuntary bowel and bladder evacuations; the pulse grew weaker, respirations shallower, the abdomen became more and more distended, and the patient died at 9:45 on the night of July 25. At no time was he rational, and during the last three or four days but rarely recognized those round about him. During his stay at the hospital his temperature ranged from 100.2 to 102.4, with the exception of a drop to 98.3 on the morning of July 21. His pulse ranged between 108 and 140.

The apparently great polyuria was difficult to explain. The following theory has suggested itself to me: For three weeks the patient had been very sick with no skilled attendant about. His wife, though willing, was not qualified to observe keenly. As he passed urine, she believed that all was well, and paid no heed to the quantity. Owing to his sluggish mental condition, he passed but a small portion of the urine that was in the bladder. As a result, the bladder gradually lost its tone and became greatly dilated. Shortly after systematic catheterization was begun, the bladder regained its tone, and far less urine was obtained than at first. I am therefore led to believe that the polyuria was far more apparent than real. Clinical diagnosis: Acute general miliary tuberculosis; dilatation of bladder.

Autopsy (July 25, 1909, 11 p. m., one and one-half hours after death).—Body that of a large emaciated man. Panniculus adiposus very slight. On opening the abdomen (which was done first in this case), the intestines were found to be enormously distended. Save for some congestion in the ileum, they were normal throughout their whole extent. Peritoneum normal. One enlarged mesenteric gland. Pancreas normal.

Left Kidney: Scattered through the cortex and medulla were several (15 to 20) gray masses, slightly elevated above the surface of the kidney substance and of denser consistency. These areas were about three times the size of a pinhead and resembled gray tubercles. In some the center appeared to be undergoing caseous degeneration.

Right Kidney: Half the normal size. Color normal in central portion, yellowish-gray at each end. Capsule stripped off easily, showing at both poles a collection of waxy yellow matter raised above the surface of the kidney. The surrounding kidney tissue was pale. Section of the kidney along its convex border opened into two cavities, one at each end lined with caseous matter one-third of an inch in thickness and containing some detritus. These cavities opened into the pelvis of the kidney. The cavities were irregular in outline. The central portion of the kidney was nearly normal save for a few scattered tuberculous areas. The pelvis was not affected.

Spleen: A few areas, suggestive of miliary tubercles.

Liver: Normal.

Heart: Small, considerable fatty deposit. Heart muscle and valves normal. Pericardium normal.

Lungs: Unduly pale (countryman?), and both showing strong adhesions of moderate extent at the apices, but none elsewhere. Both apices showed somewhat pigmented depressed scars, 2 inches each, surrounded by emphysematous areas. On section apices showed old healed tuberculous scars with considerable fibrous tissue formation. Beginning outside these areas the whole of both lungs from apex to base was studded with millions of gray miliary tubercles. At the left base a few were *going on* to caseation. The lungs as a whole felt as though full of shot.

Brain: Not examined.

Anatomic Diagnosis: Old healed bilateral apical pulmonary tuberculosis; *bipolar caseous tuberculosis of right kidney;* beginning tuberculosis of left kidney; possible tuberculosis of spleen.

The chronologic order of events seems to have been as follows: An old healed apical tuberculosis; mobilization of the bacilli very probably because of violent physical effort when house-building; lodgment of bacilli in right kidney with establishment of renal tuberculosis and appearance of bladder symptoms referred to in history of case; spread of infection to left kidney; breaking down of areas in right kidney and discharge into a vein giving rise to general dissemination throughout the lungs and without doubt throughout the central nervous system as well.

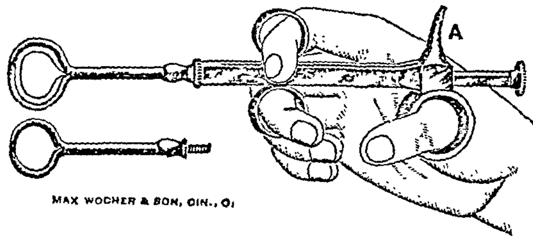
A NEW TONSIL-SNARE *

H. H. MARTIN, M.D.

SAVANNAH, GA.

I have been using with much satisfaction for the past two years the tonsil-snare shown in the accompanying illustration. I claim nothing original for this instrument, as it is simply a modification of the Krausmueller-Peters snare with the Vedder tip, but the modification is such and the instrument is so solidly constructed that it can be used in the same manner and with the same degree of lateral pressure as the Mathieu tonsillotome.



The thumb-ring is very broad to prevent injury to the thumb; there is also an extra thumb-hold in case both hands should be required for the écrasement. The instrument is used in exactly the same manner as the Mathieu tonsillotome, except that the tonsil, after being thoroughly freed from all adhesions, must first be seized with a long tenaculum hook which is entrusted to the assistant who makes gentle traction while the operator handles the snare and the tongue-depressor; in case both hands are required in the écrasement the tongue-depressor can be laid aside as soon as the base of the tonsil is well engaged by the wire loop.

The construction of this instrument is so simple that it can be easily taken apart for cleaning.

DETAILS IN TWO COMMONLY USED URINARY TESTS

F. H. CHURCH, A.M., M.D.
UTICA, N. Y.

Those using the Jaffé test for the identification of indican or the indoxyl sulphates in the urine frequently meet an equivocal result. Instead of the expected indigo-blue-colored chloroform solution, the solvent takes on a reddish or reddish-violet tint. This may be due either to indigo-red or, more commonly, to the presence of iodids in the urine. In the latter case, if the iodid is present in large amounts, it may be identified by adding starch water and acidifying directly. If the iodid is present only in small amounts, the chloroform should be removed with the pipette and placed in another test-tube. A little starch water is added and the material made alkaline by the addition of a little sodium or potassium hydroxid. The iodid of the alkali is formed and goes into solution in the starch water. Now on the addition of a little acid the iodin is set free with the characteristic starch-iodin reaction.

According to the customary directions in the text-books for the performance of the Gerhardt test for aceto-acetic acid, on the addition of the ferric chlorid solution to the urine a marked and obscuring precipitate of phosphates is usually obtained. This may be avoided and much time and temper saved by the chemist's simple expedient of adding the urine drop by drop to 10 or 15 c.c. of the ferric chlorid solution. In this way it is also possible to get a rough idea of the amount of the aceto-acetic acid present. If this is present in quantities it will give a strong Bordeaux red coloration with the addition of a very few drops of the urine; otherwise this coloration will not be present until 1 or 2 c.c. of the urine have been added.

Furthermore, it is possible to vary the strength of the reaction by varying the acidity of the ferric chlorid. After the reaction is performed and in the presence of a weak or indeterminate result, the addition of a very little dilute acid or alkali will have a tendency to accentuate the color. The material may then be halved and one tube boiled. The diacetic acid is, of course, broken up and the red reaction clears up just as it would on standing for twenty-four or forty-eight hours. These facts hold for the behavior of the diacetate of ethyl in aqueous solution as well as the acid or more probably its esters in the urine.

Professional Secrecy and Accident Insurance.—An article in the *Presse Médicale*, April 17, by a professor in the law department of the university at Montpellier and a member of the medical faculty, discusses this subject and suggests that in making out a certificate in regard to an accident, it should be handed when completed to the patient himself or his representatives. By not giving the certificate to any one but the victim of the accident, the physician is relieved from the risk of breach of the professional obligation to secrecy. The certificate should be read to the victim or his representatives and the technical terms explained to them so that they can not plead ignorance of their meaning later. Unless objective signs of a pathologic taint, not affecting the trauma, are discovered, it is unnecessary to certify to it, and the patient's statements in regard to a pathologic past for which no objective findings can be detected should be regarded as confidential. The discussion was suggested by a recent case in which a workman sued the physician for $400 damages because in his certificate he mentioned the presence of gonococcal urethritis. The case was non-suited finally.

TORSION OF PEDICLE OF AN OVARIAN CYSTOMA IN A YOUNG GIRL

M. BORNSTEIN, M.D.
MILWAUKEE, WIS.

A number of cases of ovarian cysts with twisted pedicles in girls below the age of fourteen are to be found in medical literature. Nevertheless, there is a common liability of overlooking this condition and in differentiating it from the more common inflammatory conditions in the lower abdomen. The following case should be of interest:

History.—B. S., female, aged 13; had never menstruated, but for three months past had complained of periodic attacks of pain, usually at the end of each month, starting in the right knee, appearing in the thigh and groin of the same side. Right hip-joint was normal. A physician diagnosed the first attack one of appendicitis but operation was refused. On the evening of March 31 she had a similar attack with a sharp pain in the right iliac region; developed fever and vomited. She was examined next morning, but her physician could find no local tenderness on palpation. The abdomen was distended and vomiting continued; the pulse became rapid and feeble.

Operation.—She was admitted to Mount Sinai Hospital on the evening of March 31 and operated on in the clinic of Dr. H. Greenberg. Abdomen was opened over the right iliac fossa. A local peritonitis was present. The appendix appeared normal but contained several dried-up concretions. Palpation disclosed a large cystic mass springing from the right side of the pelvis. It was found to be a large ovarian cyst, about the size of a man's head, with its pedicle completely twisted. The cyst was emptied and removed. Its contents were fluid and straw colored; the wall bluish and contained several yellowish, thickened masses. The appendix was removed and the abdomen closed.

During the same month Dr. Greenberg operated on a young woman (24 years old) for the same trouble. She was brought in with a diagnosis of acute appendicitis. Incision disclosed a blackened ovarian cyst with a completely twisted pedicle. Both patients have been discharged, cured.

Therapeutics

THE PREVENTION OF CONTAGION

Perhaps the most valuable service a physician renders is the prevention of the spread of contagious disease in the family of his patient, and the prevention of the spread of disease in the community. While Boards of Health assume the responsibility of preventing the spread of the contagion, it is only in exceptional instances that they can assume the whole responsibility, and if the physician who has charge of the patient is not efficient in his sanitary measures, the advice, orders and restrictions of the Board of Health become almost valueless. Therefore, it is not only the highest aim, but it is the duty of the attending physician to isolate the patient and to prevent the spread of the contagium that others shall not acquire the disease.

To prevent contagion properly, the most important prerequisite is that the physician shall understand the means by which the contagium of each particular disease is spread. Dr. A. H. Doty, Health Officer of the Port of New York, in the *American Journal of the Medical Sciences*, July, 1909, discusses this subject, and his long years of experience plus his efficiency as health officer makes his advice and his scientific conclusions most valuable.

Yellow fever is transmitted by the mosquito only, and clothing, bedding, and even the excretions of the patient do not carry the infection. Doty believes that the mosquito is the necessary medium for malarial infection, and does not believe that the emanations from swamps and stagnant water can produce it. Consequently these two diseases, and the former especially, may be prevented by any means that prevents mosquito bites, and an infected patient may be prevented from infecting mosquitoes by surrounding him with mosquito netting, or by keeping him in rooms which are mosquito proof, and such management will prevent the infection of others.

It has been proved that plague is not transmitted by fomites, but by the rat through the intermediary carrier of fleas.

Doty believes that there is no proof that clothing, rags, etc., constitute an active agency in the transmission of smallpox, typhus, measles and scarlet fever, and believes that in instances of the outbreak of these diseases that seem to show such means of the transmission of the contagium may always be, by careful investigation, traced to positive active sources of contagium. The clothing transmission theory of children's diseases especially is gradually being disproved by school inspection by medical men. This school inspection has shown that children who are apparently well are really carriers of the various children's diseases. This is especially true of diphtheria, and even of scarlet fever and measles. Children are often ill several days before they show sufficient symptoms to be either sent home from school or to be retained at home by their parents, and during this period of the early stage of the disease they are direct transmitters of the infection. It is also now a well-known fact that patients who have recovered from diphtheria may carry germs in their throats for weeks and even months, and are direct distributors of infection. Typhoid carriers are now known to exist perhaps in every community, and the contamination by their excretions of water and milk supplies has been proved beyond question.

Doty says that, however dirty, soiled or nasty rags, that come from all parts of the world, may be, he has yet to find conclusive or satisfactory evidence that either domestic or foreign rags act as a medium of infection.

He does not believe that paper money or coins, however filthy and old, are transmitters of infection. Otherwise bank clerks and treasury department clerks would be constantly subject to infection. As a matter of fact, they are subject no more to contagious diseases than are men and women in other employments. Careful investigations by W. W. Hilditch, of the Sheffield Laboratory of Bacteriology and Hygiene at Yale University, has caused him to come to the conclusion "that money constitutes an unimportant factor in the transmission of disease."

A senior student in the Yale Medical School two or three years ago also investigated bacteriologically a series of soiled public library books, and his investigations showed that the transmission of disease by this means must also be very rare.

Contagium must then emanate ordinarily from the patient himself and from his various secretions or excretions. Which one of these carries the greatest amount of the particular contagium depends on the particular disease. Certain it is that not sufficient hygienic or sanitary care is taken by the physician, nurse and family of the patient's secretions and excretions. Ordinary disinfection of stools and sputum with chlorid of lime, carbolic acid, corrosive sublimate and even formalin solutions have been proved not to kill specific bacteria in the central parts of the excreted masses. In other words, allowing sputum and feces to stand, even for several hours, in even strong antiseptic solutions, is an ineffectual method of killing the germs of infectious or transmissible diseases. To be effectual, discharges of all kinds must be thoroughly broken up into minute particles before antiseptic solutions can be guaranteed to kill all germs. The disinfection of privy vaults by the usual methods is simply futile, and deep privy vaults in villages and country towns where there are no sewerage facilities are dangerous to the community in proportion to the depth of the vault. The nearer to the surface of the ground and the more the air and sunlight reaches the deposits, the less the likelihood of drinking water contamination and of persistence of life in pathogenic germs.

All discharges from the mouth, throat and lungs should be received into paper sputum cups. Once or twice a day, oftener if necessary, the cup and the contents should be burned, the container washed in an antiseptic solution, and a new cup given the patient. Discharges from the nostrils should be into gauze napkins, and these should be placed in a paper bag at the head of the bed, and the bag and contents burned. Cleansing pieces of cloth or gauze for the mouth and nose should receive the same treatment, viz., be placed in paper bags and burned.

The urine should be passed into vessels that contain 1 to 500 bichlorid solution, or other strong antiseptic. The urine should then stand in this vessel, which should be covered, for an hour. It is then absolutely disinfected, and may be poured into the closet.

The bowel discharges should be into vessels that contain strong bichlorid of mercury solutions, or chlorid of lime solutions. The fecal clumps should then be thoroughly broken up with a stick, and boiling water, in large amount, poured into the mixture of feces and antiseptic. Enough of the boiling water should be used to raise the mixture almost to the boiling point. After an hour the contents of the receptacle may be considered aseptic and may be poured into the closet. This treatment of the feces should be followed out in typhoid fever, bowel infection, acute diarrhea, cholera, dysentery, acute tuberculosis, intestinal tuberculosis, and in intestinal cancer.

All cloths used in cleansing the body of the patient should be put into paper bags and burned. The clothing of the patient, the bed clothing and the clothing of the nurse should be boiled, if clothing is washable, and what is not washable should be baked.

The nurse should cleanse her hands with weak corrosive sublimate solutions every time that she has in any way come in contact with possible sources of contagion from the patient.

Ideally a sick-room should be flyless; in other words, a fly is an abomination, and the sick-room should be so screened that it will be impossible for flies to penetrate it, whatever the disease from which the patient is suffering. If a patient is out of doors for pneumonia, tuberculosis, or other fresh air treatment, the sputum receptacles should be so arranged or covered that it is impossible for flies to come into contact with the sputum.

The methods here advised being carefully carried out, there will be little necessity for the fumigation of rooms and houses with either sulphur or formaldehyd, which fumigations really carry with them a false sense of security and predispose to carelessness by the nurse and family in the cleanliness and hygiene of the patient and his surroundings.

FREQUENCY OF HEALED TUBERCULOSIS OF THE MESENTERIC GLANDS

Warthin[1] has carefully examined a large number of lymph nodes, primarily in order to determine the anatomic type of the given gland, and one noteworthy demonstration is the constant occurrence in the mesenteric and retroperitoneal lymph nodes of adults of small hyalin masses. These hyalin masses stain red with acid dyes (eosin and fuchsin) and occur in any part of the node, more frequently, however, in the cortex; they are usually round with sharp borders, varying in size from minute microscopic points to small masses visible to the naked eye. In the larger masses a few nuclei are present; the smaller may be wholly devoid of nuclei, suggesting their being older, while the larger show various stages of a hyalin change in the connective tissue replacing some lesion. These hyalin masses are hyalin scars. In the center of larger masses small deposits of lime salts often occur and reactions for iron may also be obtained. The hyalin masses are easily distinguished from the diffuse hyalin change of the stroma of atrophic nodes and also from hyalin blood vessels.

The interpretation of these masses is an interesting question. Warthin believes that they can not be explained as the result of retrogressive changes associated with senile atrophy and fatty infiltration, because they occur at all periods of life, even in the young, and unassociated with other retrograde changes. Indeed, nodes with hyalin masses may be markedly hyperplastic. Warthin's interpretation is that the hyalin masses in the majority, if not in all of the cases, are tuberculous in nature. He bases this conclusion in part on the fact that in advanced pulmonary tuberculosis the abdominal lymph nodes constantly show nodules in all steps of transformation from the young and miliary epithelioid tubercles to small deeply staining hyalin masses, showing conclusively, it would seem, that hyalin transformations like those described can result from the healing of small tubercles. In other cases of small masses in the mesenteric nodes undergoing hyalin change, a minute caseous center or a single giant cell would serve to indicate the tuberculous nature of the process, even though the hyalin transformation was far advanced. In two cases active miliary tubercles associated with miliary hyalin masses in various stages of formation from tubercles were found, while tuberculosis was not discovered in any other part of the body, indicating that primary mesenteric tubercles may heal with formation of hyalin masses. In most of the cases in which hyalin masses were found, no active tubercles were discovered in the body. But even here the form and character of the hyalin mass indicated healed tubercle. According to Warthin, these hyalin masses are most common in the mesenteric, cervical and bronchial nodes, but are rare in the axillary nodes except in cases of tuberculosis of the breast. This distribution is also suggestive of their tuberculous nature. They are rare in the tonsils.

Assuming that the hyalin masses represent healed tubercles, and in view of the fact that they occur so constantly in the abdominal nodes, the conclusion seems forced on us that the tubercle bacilli enter the body through the intestine much more commonly than has been assumed. In cases of pulmonary tuberculosis the bacilli may gain entrance to the mesenteric nodes from the swallowed sputum carried down into the intestine, but in the absence of pulmonary or other foci of tuberculosis the bacilli must have been introduced either in dust swallowed with saliva or in food.

If the hyalin masses actually represent healed tuberculous lesions, at least in the majority of cases, then, it would seem certain that all adults receive tubercle bacilli through the intestine; and, if this be accepted, then it would be reasonable to attribute pulmonary tuberculosis, at least in many cases, to enterogenous origin, because if bacilli so commonly enter the mesenteric and retroperitoneal lymph nodes they may readily pass on through the thoracic duct to the lungs and bronchial nodes.

TRANSMISSION OF SLEEPING-SICKNESS

Probably the two most important problems now confronting those who are investigating sleeping-sickness are: (1) the method by which tsetse flies transmit sleeping sickness and other trypanosomatic infections; (2) does the trypanosome undergo a complicated (probably sexual) development in the fly?

For some time the belief has been prevalent that transmission is of the simple mechanical type, i. e., that the fly draws infected blood into its proboscis and stomach and later, when feeding on a second animal, injects some of the contaminated blood, thus transferring the disease. This conclusion has been based chiefly on the fact that the flies seemed to lose the power of transmission soon after feeding on an infected animal.

A number of experiments, however, seemed to cast doubt on the mechanical method as being the sole process, and the question has arisen as to whether there may be two methods—the first the mechanical, operating soon after the feed on an infected animal, and the second a "biologic" method, coming into action later and depending possibly on a sexual evolution of the parasite in the fly, as happens in relation to the mosquito and malaria. Trypanosomes disappear from the alimentary tract of the fly so soon after its feed on infected blood that Bruce considered it virtually impossible that mechanical transmission alone could explain the situation.

---

[1] Sixth International Congress of Tuberculosis.

Recent experiments of Kleine, which have been confirmed by Bruce, contradict some of the previous results.[1] In Kleine's experiments, the flies, *Glossinæ palpales*, were caught fresh from Nature, fed once on monkeys *(Cercopithecus rufoviridis)* which were infected with sleeping sickness (*Trypanosoma gambiense*) and then tested on fresh monkeys every second day. Large numbers of flies were used; thus 336 fed on the first monkey and 225 on the last. All the monkeys became infected, the last one twenty-two days after the beginning of the experiment. In another experiment by Taute, which is reported by Kleine, infection was produced on each of the first three days after feeding. From the fourth to the tenth day no infection resulted. The flies then became infective again, and produced disease from the eleventh to the forty-fourth day.

From these experiments it is concluded that transmission is not purely mechanical, but that flies are true hosts for the trypanosomes. From other experiments with flies, hatched in the laboratory, Kleine concludes that the period of development, or incubation period, in the fly is about twenty days, or a little less. These are important experiments and seem destined to be of great significance for the campaign against sleeping sickness.

Much of the experimental work with tsetse flies and trypanosomes has suffered from lack of sufficient control. Too often in dealing with flies caught from Nature, the possibility of some of them being naturally infected (an event known to occur) has been neglected. Also, as Novy has emphasized, and as Minchin has virtually proved, tsetse flies may harbor, naturally, nonpathogenic as well as pathogenic trypanosomes, a fact which impairs the value of a great deal of the microscopic work which has been done. As a means of avoiding the accident of dealing with naturally infected flies, the custom of using flies which have been bred and raised in the laboratory is being resorted to. Here, again, the possibility of the hereditary transmission of trypanosomes may be a confusing one, and one which is so fundamental that it demands early determination. This is appreciated by many workers in the field.

For unimpeachable work along these lines it would seem to be an unqualified necessity to deal with pure cultures of the parasites, as Novy has suggested, with flies which are known to be absolutely free from trypanosomes, and with experiment animals which have never been exposed to trypanosomatic infection. The pertinence of these points is doubtless realized by those who are engaged in the practical study of the problems. The difficulties are great, but, in spite of this, the progress which has been made is of no small magnitude.

A STANDARD CURRICULUM FOR MEDICAL COLLEGES

It is extremely doubtful whether the medical profession as a body really appreciates the far-reaching influence of the splendid work that is being done by the Council on Medical Education of the American Medical Association. The collection of data regarding medical colleges, students and graduates, begun by THE JOURNAL nine years ago, and of data giving the results of state licensing boards' examinations, begun by THE JOURNAL six years ago, revealed the great need of such a permanent committee as the Council on Medical Education and, in fact, furnished a foundation for the council's work. By the actual inspection of medical colleges, by annual conferences with members of state licensing boards and in other ways, the council has extensively developed these statistics, obtained an enormous amount of other valuable educational data and has used them in a most practical and effective manner. Reports of much of the work of the council are published regularly in THE JOURNAL, but from lack of space much more, although none the less valuable, can receive only brief mention.

Probably no work which the council has done is more important than the preparation of a standard curriculum for medical colleges, the report of which is referred to on page 1115. In the preparation of this standard, everything possible was done to insure that it would represent the harmonized ideas, if not the ideals, of as large a number as possible of the leading medical educators, who were selected from all sections of the country. The subjects of the medical curriculum were arranged in ten groups, to be taken up by subcommittees for which ten chairmen were carefully selected. These chairmen were asked to name fifteen leading educators in their particular departments, and from these lists nine other members for each subcommittee were secured. A suggestive outline of the points to be considered was prepared; but each subcommittee was left free to take up the study of the problem relating to its particular subject in its own way, and, after careful study and deliberation, to submit a report to the council, making specific recommendations regarding that particular subject. The work was entered into with an energy and enthusiasm that were astonishing, numerous meetings of committees were held and a large amount of systematic correspondence was carried on, not only with those comprising the regular subcommittees, but also with numerous collaborators and corresponding members. More than an entire year of close application was spent before the reports were finally completed. In order that the work of the subcommittees might not be too much at variance, a preliminary meeting of the ten chairmen was held and, just before the final reports were prepared, these chairmen met again and determined on the curriculum which was to be recommended. The standard presented, therefore, represents the work not only of the one hundred educators who made up the ten subcommittees, but also of many others who acted as collaborators and corresponding members. It needs but a glance at the list published in the Department of Medical Education to show the high standing and reputation of those who cooperated in the preparation of the curriculum and the breadth of the field covered.

---

[1] These experiments are described in the *Bulletin of the Sleep-* [illegible] . 7, 1909. Prof. Kleine's article "*Weitere* [illegible] *chtungen über die Entwicklung von Try-* [illegible]" appeared in the Deutsch. med. Wchnschr., May 27, 1909, pp. 924-925. Bruce's announcement appeared in a letter to the Royal Society.

Since there has begun an extensive reconstruction of medical teaching in this country, as illustrated by the numerous mergers of colleges, and the rapid movement toward higher standards of preliminary education, the presentation of this standard curriculum is all the more important and timely. It will bring about not only a greater uniformity of curricula in our medical colleges, but will result in each branch being allowed an amount of time proportional to its value and importance. It will also tend to prevent the overcrowding of the curricula with non-essential subjects and details. Although absolute uniformity of curricula for all colleges is not to be recommended, comparative uniformity is highly desirable in the interests both of medical education and of interstate reciprocity in the licensing of physicians.

The standard recommended reflects great credit on the Council on Medical Education as well as on the members of the various committees who have contributed so much valuable time and careful thought to its preparation. The report is well worth a careful study by those interested in modern scientific medical education.

PELLAGRA

Although it is hardly more than two years since the presence of pellagra in the southern states was recognized, it has been found that the disease is a widespread one and new cases and localities of its occurrence are being constantly reported. It is, moreover, not confined to any one section of the country and is being discovered in such widely separated localities as Massachusetts and Arkansas and possibly even further west. It has appeared in at least three state hospitals for the insane in Illinois, and in one or two of them in such numbers as to assume the proportions of a small epidemic. It has not been reported as yet from any large number of northern localities and its distribution seems somewhat local. Probably, as in the case of some other new disorders to which attention has been suddenly called, the apparent sudden prevalence is due, partly at least, to faults of previous observation. Thus Dr. Lavinder, whose report has been noticed in THE JOURNAL,[1] mentions the fact that the medical staff could recall that cases had been in the institution years before the present outbreak in the Illinois State Hospital at Bartonville, and very probably this is the case elsewhere to some extent. The late accounts, however, would indicate a much greater prevalence than ever before, and it is hardly probable that such local outbreaks of the disease could have occurred in any locality without being observed and properly diagnosed. Asylum physicians have been acquainted with the disease, at least in their reading, and some have been on the lookout for it without being able to identify it in the patients under their care. At most, the cases that have occurred must have been scattered and only sporadic ones.

It may, therefore, be considered a new disease in the United States, and its occasional occurrence heretofore may perhaps be explainable by such idiosyncrasies as are reported in Dr. Hewitt's patient and his relatives in his communication published in this number on "Pellagra in Virginia." While predisposition has been recognized in the etiology, an idiosyncrasy to corn products, such as that reported by Dr. Hewitt, is novel and suggestive. Besides possibly accounting for sporadic cases it would indicate the possibility of some toxic element in the grain that may not be ordinarily effective in producing the disease unless its virulence is greatly enhanced from some cause or other, or the individual is specially susceptible. Case-histories should be carefully studied as to this point, and the physician who runs across a case in his practice should give careful attention to the family history as well as the personal antecedents of the patient. The local distribution should be thoroughly traced and its occurrence in the immigrant population of the asylums should also be carefully studied. There is no evidence, according to Dr. Lavinder, that the disorder had any connection with the feeding of the patients in the Bartonville hospital. It must have originated elsewhere and before their admission. He says that he is unable to assign any satisfactory local cause for the extent of the disease in the Bartonville epidemic, and that the housing, feeding and care of the patients in the institution are above criticism. The facts that practically all of the cases of pellagra in this country have been found in institutions for the insane, and that they present the severe type of the disease usually seen in a late stage, suggest that these cases are old ones which have gravitated to the asylums because of the dementia characteristic of the disease. In at least one case of pellagra in an advanced stage, this had presumably occurred, for the patient had within six months arrived in this country from a pellagrous district of Europe.

We have, therefore, a new public health problem which, though extensively studied in Europe for many years, cannot be regarded as definitely solved. The observation of the disease in its beginnings will have to be made largely by the general practitioner, and it seems probable that there will be considerable opportunity for the profession to study the disease in this country. While pellagra is insidious in its course, the symptom-complex is fairly characteristic even in its early stage. This complex consists of gastrointestinal disturbances with "bald" red tongue, erythema of the exposed extremities and center of cheeks, spinal irritation, with probable pain in back and disturbance of the knee-jerks, and mental depression of varying degree. The skin symptoms, in themselves unimportant, give a very significant clue to the diagnosis, for, in the first place, there is no other disease with cutaneous lesions presenting a closely similar group of constitutional symptoms, and in the second place the cutaneous lesions themselves, after they have become well developed, are unlike those of any other cutaneous disease. The diagnosis must be made early in the disease if the patients are to be saved. Practitioners should be alive, therefore, to the possibility of its occurrence. In doubtful early cases it would seem to be the part of wisdom to make a provisional diagnosis of pellagra, for nothing will be lost by removing corn products from the diet and giving the patient the hygienic treatment indicated.

---

[1] The notice of Dr. Lavinder's report which should have appeared in the department of General News was through an oversight published as editorial matter in THE JOURNAL, Sept. 25, 1909.

Medical News

ARKANSAS

National Guard Notes.—Major L. R. Ellis, Hot Springs M.-C., A. N. G., announces that arrangements are being made to increase the membership of the hospital corps of the guard to 36, the number allowed under the new law.

Personal.—Dr. Avery Moore, formerly state auditor, has resigned as a member of the state tax commission.——Dr. J. E. Quidor, Little Rock, has been appointed a member of the Pulaski County Board of Health, vice W. H. Abington, resigned.

Society Organized.—Dallas County Medical Society was organized at Fordyce, September 9, and the following officers were elected: Dr. Claiborne J. March, Fordyce, president; Dr. O. R. Kelley, vice-president; Dr. Thomas L. Rives, Fordyce, secretary; and Dr. William L. Worthington, Fordyce, treasurer.

Medical Schools Open.—The Medical Department of the University of Arkansas, Little Rock, opened September 30.——The College of Physicians and Surgeons, Little Rock, opened October 1. Drs. Luther D. Reagan. Little Rock, and George H. Martindale, Hope, have been added to the faculty of the college.

Dropped from Register.—Dr. George A. Hinton, Hot Springs, is said to have been dropped from the list of registered physicians at that place, August 6, by the superintendent of the government reservation, acting under instructions from the Department of the Interior. He will be denied the privilege of prescribing the waters until his name is restored to the list.

New Medical Practice Act in Effect.—The new law regulating the practice of medicine went into effect August 6. Under the provisions of this law the number of state medical board meetings is cut down to two a year; and the revocation of licenses for criminal and persistent inebriety, the practice of criminal abortion, either principal or abettor; for the conviction of crime involving moral turpitude; for the public advertising of special ability to treat or cure chronic or incurable diseases; for representation to a board of any license, certificate or diploma, illegally or fraudulently obtained, or the practice of fraud or deception in passing an examination, is authorized. The board is also authorized to make agreements of reciprocity with the examining boards of other states.

CALIFORNIA

Nurse Dead in Hospital Fire.—St. Caroline's Hospital, Redding, a two-story frame building, was destroyed by fire September 19, with a loss of $18,000. The seven patients were removed in safety, but one nurse was burned to death.

Hospital News.—The new Methodist Hospital, Los Angeles, with accommodation for twenty patients, was opened September 8.——The contract has been let for the construction of a new Childrens' Hospital, San Francisco, to cost about $200,000.

Tuberculosis Stamp.—The California Association for the Study and Prevention of Tuberculosis has issued a special stamp, designed to serve the same purpose as the Red Cross stamp that was sold throughout the country by millions last year.

Sub-Society to Be Formed.—On September 17, Kenneth A. Millican, president of the Alameda County Antituberculosis Society, and Dr. William Von Adelung, first vice-president of the society, went to Alameda and formed a sub-society in that city which will be under the direction of Dr. Weston O. Smith.

News of the Day in Hospitals.—The California Hospital, Los Angeles, has introduced permanently the dissemination of the news from the daily press to the patients of the institution. The contents of the newspapers of the day are communicated to the nurses at luncheon and imparted by them to the patients later in the day.

Guests of Faculty.—The annual banquet of the students of the graduating class of the Oakland College of Medicine and Surgery, by the faculty of the college, was held September 14. Dr. Hayward G. Thomas, president of the college, acted as toastmaster, and Dr. Creighton Wellman, professor of tropical medicine, gave an address on "Tropical Diseases."

Personal.—Sir Augustus Waller, director of the physiologic laboratory of the University of London, delivered a series of five lectures at the University of California, Berkeley, beginning September 20, on "Physiology, the Servant of Medicine."——Dr. Newell H. Bullock has been appointed medical inspector of schools of San Jose.——Dr. Claiborne W. Evans, Modesto, has returned from Europe.

CONNECTICUT

Unlicensed Practitioner Fined.—George A. Wilbur, alias Albert Cole, arrested in New Haven on the charge of practicing medicine without a license, is said to have been found guilty and fined $100 and costs.

Personal.—Dr. William S. Hulbert, Winsted, medical examiner, had his left eye enucleated August 19.——Dr. William F. Wood, Danbury, is said to have been adjudged insane and committed to the State Hospital, Middletown.

Tuberculosis Commission Organized.—The State Tuberculosis Commission, at its meeting for organization August 26, elected Dr. John P. C. Foster, New Haven, chairman, and George I. Allen, Middletown, secretary. The commission applied for rooms for a permanent office in the capitol.

State Board of Health Organized.—At the annual meeting of the State Board of Health, the following officers and committees were appointed: President, Dr. Edward K. Root, Hartford; secretary-treasurer, Dr. Joseph H. Townsend, New Haven; director of laboratory and bacteriologist, Dr. Herbert W. Conn; member of board of examiners and embalmers and registrar of physicians for State Board of Health, Dr. Joseph H. Townsend.

Tuberculosis Legislation.—The state legislature has enacted three important antituberculosis laws—the first prohibiting spitting in public places; the second, requiring physicians to report to the local health officer all cases of tuberculosis coming under their care, and giving such instructions as will provide for the safety of persons occupying the same house or apartment, and the third appointing a board of directors to establish county homes for the care and treatment of those suffering from tuberculosis. It is proposed to establish three of these homes. An appropriation of $175,000 has been made for that purpose, with $75,000 additional for maintenance. This appropriation with $50,000 given to aid the Gaylord Farm Sanatorium, Wallingford, Wildwood Sanatorium, Hartford, and Undercliff Sanatorium, Meriden, make a total of $300,000 appropriated by the state for tuberculosis work during the next two years.

DISTRICT OF COLUMBIA

Conflicting Opinions.—The name of John R. Early, the supposed leper, who has been receiving a pension of $72 a month because of total disability, is said to have been stricken from the roll of the pension bureau, as he has been found entirely free from the disease. Dr. G. Armauer Hansen announced September 24 that he had found the bacillus of leprosy in a specimen of Early's skin sent to him for examination.

Personal.—Dr. A. H. Sutherland has been appointed assistant in psychology at the Government Hospital for the Insane, Washington.——Major Frederick S. Russell, U. S. A., professor of pathology in the Army Medical School, and curator of the Army Medical Museum, has been selected to succeed Dr. Joseph J. Kinyoun as professor of pathology and bacteriology in George Washington University.——Dr. William P. Wood of the Episcopal Eye, Ear and Throat Hospital, by presence of mind prevented a fire panic in the institution September 8, but sustained severe burns of the hand in extinguishing the fire.

ILLINOIS

Personal.—Dr. Albert J. Roberts, Ottawa, has been reelected physician of LaSalle county.——Dr. Emery W. Goembel, Rockford, has been appointed physician of Winnebago county.——Dr. Walter S. Eshbaugh, Marengo, has been appointed deputy coroner of McHenry county.

Chicago

Personal.—Drs. G. F. Fiske, L. L. McArthur, A. D. Bevan, John B. Murphy and G. Paull Marquis have returned from Europe.——Dr. William W. Meloy was operated on for appendicitis at the Passavant Hospital, September 19.

Municipal Laboratory Moves.—The municipal laboratory has been moved from the corner of Franklin and Madison to 218 Washington street, where it has leased 2,000 more square feet of space at an annual reduction of $2,000 in rent.

Buys Postgraduate School.—Financial control of the Post-Graduate Medical School and Hospital of Chicago, which has been held by Dr. Franklin H. Martin since its organization in 1888, has been sold to Dr. William L. Baum, a member of the board of directors for fifteen years, and for several years treasurer of the institution. Dr. Emil Ries has been elected secretary, vice Dr. Franklin H. Martin, resigned, and Dr. Otto J. Stein a director, vice Dr. Frederick A. Besley, resigned.

KANSAS

Personal.—Dr. Clifford C. Nesselrode has been appointed city chemist and bacteriologist of Kansas City.——Dr. Elmore S. Pettyjohn, Topeka, has been elected a vice-president of the medical section of the National Fraternal Congress.

Bakeries Must Be Sanitary.—Cardboard posters have been sent out by the secretary of the State Board of Health for distribution to the bakeries, containing rules governing the sanitary condition of bakeries, which will be strictly enforced.

State Tuberculosis Exhibit.—The Kansas Tuberculosis Exhibit, which has been on exhibition in various towns of the state for about six weeks, is attracting a great deal of attention and a schedule has been arranged for to the first week in January.

MARYLAND

Baltimore

Acquitted.—Dr. Louis M. Harrison, charged with passing bogus checks, and confined in jail since last May, has been acquitted in the criminal court.

Spratling May Resign.—It is rumored that Dr. William P. Spratling, professor of physiology and nervous diseases in the College of Physicians and Surgeons, is about to resign, and will open a sanatorium at Summit, N. J.

Mayo to Lecture.—Dr. Charles H. Mayo, Rochester, Minn., will deliver two lectures at the University of Maryland, November 9 and 10, on "Diseases of the Thyroid Gland," and on academic day he will receive from the university the honorary degree of LL.D.

Personal.—Dr. Frank J. Sladen sailed for Europe September 22.——Mrs. Fabian Franklin, Johns Hopkins University, has returned from attendance at the Congress of Psychology, Geneva.——The mayor has nominated Dr. William H. Welch as a member of the new charter commission.——Dr. F. E. Vest has sailed for Europe.

Harriet Lane Home.—The Harriet Lane Home for Invalid Children about to be constructed at Johns Hopkins Hospital is to cost about $200,000. The buildings will conform in construction with the rest of the hospital group. The main building will be 133x65 feet, but the entire space covered by the building and observation wards will be 133x160 feet. The building will be four stories high, with a modern roof hospital, and 102 beds, all of which will have access to open or semi-open porches.

Medical College Changes.—The annual session of the Baltimore Medical College opened September 20, with an address by Dr. Ridgely B. Warfield. The following faculty changes were announced: Dr. Alexander D. McConachie has been elected professor of diseases of the ear, nose and throat; Dr. William S. Love, professor of therapeutics; Dr. Irvin Ebaugh, professor of materia medica; Drs. Josiah S. Bowen and Frank J. Powers, associate professors of diseases of the ear, nose and throat; and Dr. A. C. Beethan, dispensary physician.

MASSACHUSETTS

Bequest.—By the will of Lucius Clapp, Randolph, $5,000 is devised to the Massachusetts General Hospital, Boston, for the establishment of a permanent free bed.——By the will of the late Patrick Cassidy, a hackman of Boston, $100 is bequeathed to Carney Hospital.

Smallpox on Liner.—The steamship *Romanic*, which arrived from the Mediterranean September 9, was held at quarantine five hours on account of two persons with smallpox being among the steerage passengers. The 1,117 steerage passengers on the boat were revaccinated.

Unregistered Practitioner Fined.—Richard H. Farrell, Everett, charged with practicing medicine without having registered, is said to have been fined $100 in the Malden court, September 10. The defendant claimed to hold an A.B. from Bellevue, and a medical degree from Boston University, but was unable to pass the state examination in March, May and August, 1909.

Infant Hygiene.—At a meeting of Boston physicians August 26, presided over by Dr. Walter B. Cannon, secretary of the committee on milk and baby hygiene, an appeal was made for new milk stations at Grove Hall and Roxbury Crossing. The following officers were elected: President, Dr. Charles W. Townsend; vice-presidents, Drs. John L. Morse, Ralph C. Larrabee and Rocco Brindisi; secretary, Dr. John M. Connolly, and treasurer and director, Walter E. Kruesi.

Floating Hospital Work.—During the ten weeks from June 30 to September 7, in which the Boston Floating Hospital was in operation, 17,665 days' service were enjoyed by babies and mothers, divided as follows: Seven thousand one hundred and twelve days' service for poor patients, day and night; 4,848 days' service for day patients; 831 days' service for other children, and 4,847 days' service for mothers.——The sixteenth season of the hospital closed September 15, with the customary cruise in the harbor.——Dr. John Warren Bell, for two years resident physician, has resigned and will return to private practice in Brooklyn.——During the season 144 children died on the boat.

MISSISSIPPI

A Deadly Trio.—The Mississippi State Board of Health has issued an illustrated poem entitled, "Three Dangerous Toughs," namely, liquor, the house-fly, and the anopheles.

Improvements at University Hospital.—In addition to the original contract on the University of Mississippi Medical Building and Hospital, Vicksburg, a contract is to be let connecting the two buildings and making such improvements and interior work as may be deemed necessary before the new building is completed.

Cocain Prescriber Fined.—Dan W. Sherrod, a colored physician and druggist of Meridian, is said recently to have been convicted and fined for illegal sale of cocain. He claims that a favorite prescription of his was cocain hydrochlorate and acetanilid, equal parts, used for ulcers and wounds, but witnesses for the state, negroes arrested in a cocain debauch, swore that they regularly obtained the drug at Sherrod's drug store.——A druggist named Thorne of the same city is said to have been convicted at the same time on a similar charge and fined the same amount—$50 and court costs.

NEBRASKA

Change in Management.—Dr. Charles L. Egbert, Glenville, has assumed management of the hospital in the Madgett Flats, Hastings, which will hereafter be known as the Egbert Hospital and Sanitarium. Dr. John W. Greenman will be in charge of the surgical department.

Personal.—Dr. Robert Henry Wolcott, Lincoln, has been appointed acting dean of the Medical College of the University of Nebraska.——Dr. F. J. Peter, Omaha, has returned from Europe.——Dr. N. T. Johnston has been appointed a member of the board of health of Upland.

Presentation to Dr. Ward.—At a luncheon given in Omaha on September 3, in honor of Dr. Henry B. Ward, formerly dean of the Medical Department of the University of Nebraska, Lincoln, who has accepted the chair of zoology in the University of Illinois, Champaign, his colleagues presented him with a gold watch.

Double Red Cross Camp.—The State Board of Health has designated Tabitha Hospital, Lincoln, as a place where counties may send indigent curable consumptives. The hospital will be known as "The Double Red Cross Consumptive Camp." It is situated in the park just north of Tabitha Hospital, and is under the medical direction of Dr. Julius H. Tyndale.

NEW YORK

The Antituberculosis Conflict.—A gift of $10,000 has been made to the fund for the tuberculosis pavilion to be erected at Albany Hospital by an anonymous benefactor. The fund now amounts to $21,000.——The Board of Health of Poughkeepsie has decided to use the Eastman house for tuberculosis patients when the weather becomes too cold to allow them to remain at Camp Comfort.——The Orleans county branch of the State Association for the Prevention of Tuberculosis has been organized with Dr. Ralph Earle Brodie, Albion, secretary.——Dr. Zina Gifford Truesdell, Warsaw, has been elected first physician of the Wyoming County Antituberculosis Society.——The state health commissioner has approved the application of the Workingmen's Circle, a fraternal organization, to establish a tuberculosis sanatorium for its members at Liberty.

New York City

New Hospital for Long Island.—The Sisters of the Poor of St. Francis will erect a hospital to cost about $500,000 at Woodhaven, Queen's Borough, to be known as St. Anthony's Hospital.

To and From Europe.—Dr. and Mrs. John Elmer Weeks, New York City; Dr. John Osborn Polak, Brooklyn, and Dr. Gustav G. Fischlowitz, New York City, have returned from Europe.——Dr. and Mrs. George W. Jacoby have sailed for Europe.

School Acquires Property.—The trustees of the New York Policlinic Medical School and Hospital have taken title to properties at 339-349 West Fiftieth street and 346 West Fifty-first street, on which they expect to erect a hospital in the near future.

Increase in Typhoid Fever.—For the week ended August 7, there were 72 cases of typhoid fever reported; for the week ended August 14, 71; for the week ended August 21, 74; for the week ended August 28, 158; for the week ended September 4, 181; for the week ended September 11, 285; and for the week ended September 18, 276.

People's Hospital.—Plans have been filed for remodeling an old-fashioned four-story and basement dwelling on Second avenue into a home for the proposed People's Hospital; the necessary improvements will cost about $15,000 and will provide for a dormitory, wards and private rooms, operating and sterilizing rooms and nurses' room.

Bequests.—Emma A. Tillotson has given in bequests $175,000 to the Woman's Medical College, the Home for Old Men and Aged Couples, St. Luke's Hospital, Bernard College, the New York Society for the Ruptured and Crippled, the Home for Incurables, the Metropolitan Museum of Art, the New York Institute for the Blind, and the American Society for the Prevention of Cruelty to Animals.

Inquiry Into Typhoid.—More than 1,000 cases of typhoid fever have been reported to the Board of Health during the past ten weeks. The distribution of the cases is such that they cannot well be attributed to returning vacationists, and it seems quite probable that the Croton water may be to blame. Thus far the Board of Health cannot ascertain that there is any more typhoid fever in the watershed than usual. It is supposed by some that the heavy rainfall in August after a long drouth was instrumental in washing infected matter into the streams that supply the city.

The Hudson-Fulton Celebration.—Medical emergency stations are being operated during the Hudson-Fulton celebration under the direction of the Committee on Public Health and Convenience, and are divided into two classes: Field hospitals, open day and night, of which there are twenty-three, and first-aid stations, located every few blocks along the route of the land parade and along the Manhattan shore of the Hudson River. These hospitals and stations are furnished, equipped and provided with doctors and nurses by the New York county branch of the Red Cross Society and by the National Volunteer Emergency Service. To supplement the regular city ambulance service, a number of extra ambulances have been secured and these are utilized to transfer serious cases to the city hospitals. Fast ambulance launches patrol the river in the vicinity of the warship anchorage and accompany the naval parade. Ambulance stations are located at several piers to facilitate the transfer of patients from the launches to the hospitals. The hospitals of the city have made preparations to increase their normal capacity to a considerable extent during the celebration. The services rendered at any of the Public Health and Convenience Committee's stations are entirely free of charge to the public. Dr. Eugene H. Porter is chairman of the Public Health and Convenience Committee.

Buffalo

Tag Day.—The yield of "Tag Day," September 18, was more than $9,100, or $1,100 more than the estimate. This amount is to be devoted to the work of the District Nursing Association.

Will Continue to Use Hospital.—The Board of Health has decided to continue using the temporary hospital for scarlet fever which was condemned by the health commissioner, and the commissioner of public works is to decide what improvements are necessary to make the building habitable until a permanent building may be built.

NEW JERSEY

Donation to Hospital.—Mrs. James M. Jarvis, Montclair, has donated $6,000 to the Mountainside Hospital in that city.

Personal.—Dr. William Todd, Tom's River, has been selected as medical inspector of the Dover township schools.——Dr. Katherine Porter has been appointed medical inspector of the public schools of Orange.

Tuberculosis Commission Named.—In accordance with the law passed by the last legislature, creating a State Tuberculosis Commission, the governor, on September 17, named as members of that body, Right Rev. James A. McFall, Bishop of Trenton; William G. Cirhauffler, Lakewood; Sidney G. M. Colgate, Orange; William C. Smallwood, Newark, and Mrs. William T. Dayton, Trenton.

August Deaths.—During August, there were 3,255 deaths reported to the Bureau of Vital Statistics, 1,040 of which were children under 1 year of age; 291 of children between 1 year and 5 years, and 742 of individuals 60 years old or over. Chief among death causes were infantile diarrhea, 656; diseases of the nervous system, 355; tuberculosis, 325; diseases of the circulatory system, 271; nephritis, 179; cancer, 164; pneumonia, 114; whooping cough, 31; typhoid fever, 29; scarlet fever, 25; diphtheria, 21, and measles, 11.

NEW MEXICO

State Railway Surgeons Meet.—At the annual meeting of the New Mexico Railway Surgeons Association, held in Roswell, September 17, Dr. John W. Colbert, Albuquerque, was elected president; Dr. George K. Angle, Silver City, vice-president; and Dr. Frank E. Tull, Albuquerque, secretary-treasurer.

State Medical Society Meeting.—At the twenty-eighth annual meeting of the New Mexico Medical Society, held in Roswell, September 15 and 16, the following officers were elected: President, Dr. John W. Elder, Albuquerque; vice-presidents, Drs. Francis T. B. Best, East Las Vegas; Robert L. Bradley, Roswell, and Leroy S. Peters, Silver City; secretary, Dr. George S. McLandress, Albuquerque; treasurer, Dr. Abraham H. Faith, Clovis; editor of the *New Mexico Medical Journal*, Dr. Francis T. B. Best, East Las Vegas; associate editors, Drs. John W. Colbert, Albuquerque; George S. McLandress, Albuquerque, and Leroy S. Peters, Silver City; and council, Drs. George W. Harrison, Albuquerque; Charles M. Yater, Roswell, and Samuel D. Swope, Deming. The next annual meeting is to be held at Albuquerque.

PENNSYLVANIA

Jewish Sanatorium Opens.—The Philadelphia Jewish Sanatoruim for Consumptives, Eaglesville, was formally opened September 22, when 10 patients were admitted. By September 25 50 patients will be cared for. The cost of the sanitarium was $40,000.

To Fight Tuberculosis.—Tuberculosis day was observed throughout Berks county, September 20, when war against the disease was begun by the Tuberculosis Aid Society. Appeals were sent broadcast throughout the county and in Reading $20,000 was raised. It is expected that the surrounding country will raise $5,000 or more. The money will be devoted to the establishment of a sanatorium for the treatment of tuberculosis.

State Society's New Flag.—At the annual meeting of the State Medical Society in Philadelphia during the present week, an official flag was unfurled at its place of meeting. This is the first official emblem in the society's history. The new banner is five feet wide and eight feet long and was the gift of the physicians of Philadelphia. The emblem has a field of the state's color, dark blue, and the state's seal in the center surrounded by the name of the society in white letters.

Enjoined from Practice.—In the case of Dr. John A. Boyd, Pittsburg, against Dr. J. O. Reed, in which the plaintiff claimed that he had bought the practice of the defendant in 1905, the latter agreeing not to engage in practice within two miles of the plaintiff's office, the judge is said to have awarded $600 damages to the plaintiff, and to have enjoined the defendant from practicing medicine in the prohibited locality.

Epileptic Hospital Investigation.—Tales of alleged brutality, mismanagement and misrule on the part of Dr. Henry M. Weeks, superintendent, and other officers and attendants of the new Pennsylvania Hospital for Epileptics and Feeble-minded, Spring City, were placed before a special committee of the board of trustees at a meeting of investigation held September 8. None of the testimony heard was made public, but it was reported that some evidence had developed to support the charges. The institution was opened one year ago and contains at present about 200 inmates, principally boys. The investigating committee is composed of Dr. George R. R. Umstad, Phoenixville; Henry W. Comfort, Falsington, and Dr. Thomas C. Detweiler, Lancaster.

Philadelphia

Released.—Dr. Joseph R. Parke, who was arrested and charged with illegally using the mails, was released of the charge recently by the Federal Grand Jury.

Personal.—Drs. James M. Anders, Alfred Stengel, Eugene L. Vansant, John H. Musser, Francis X. Dercum, George E. deSchweinitz and Donnel Hughes have returned from Europe.——Dr. J. Chalmers DaCosta is confined to the house with an affection of the eyes.——Dr. Joseph F. Harold is to fill the chair of chemistry in the Medico-Chirurgical College during the absence of Dr. George Meeker in Europe.

Typhoid's Decrease.—The report of the Bureau of Health for the first three weeks of September, concerning typhoid fever, shows that 158 cases of that disease have been reported. This is 70 per cent. less than the average for the first three weeks of September for the last three years. The mortality from typhoid fever was 248 for the year up to September 1. This is 47 per cent. less than the average mortality for the last five years.

Faculty Changes.—The following changes have been made in the faculty of the Medico-Chirurgical College: Dr. Edward B. Gleason, professor of otology; Dr. Philip Fischelis, associate professor of histology; Dr. Herbert J. Smith, assistant professor of materia medica and therapeutics, and Dr. J. Hamilton Small, assistant professor of bacteriology. Biology is to be made a part of the medical course the first year instead of being required preliminary to the course. This branch will be conducted by Charles H. Shaw, Ph.D., with special reference to the science of medicine.

Course in Public Health.—Courses in public health are being given at the University of Pennsylvania for the first time as a separate series leading to a diploma in "Public Health." The authorities of the university, recognizing the increasing demand for the services of trained men as public health officers, offer these new courses of instruction, especially designed for practical sanitation and include courses on sanitary engineering, public water supplies, theory of hydraulics, sanitary engineering of buildings, inspection of meat, milk and other animal products, practical methods used in sanitary work, personal hygiene, general hygiene, sanitary legislation, and the examination of social and vital statistics in the United States. The course of instruction covers a period of one academic year and twenty hours a week during the second term. At the close of the term all those who qualify in the final examinations will receive a diploma and will be designated as "Certified Sanitarians." Only persons holding the degree of doctor of medicine are eligible to the full course and entitled to the diploma.

TEXAS

Doctors' Building.—The Dallas Chamber of Commerce announces that a twelve-story business and office building is to be erected at Main and Poydras streets, to cost $500,000, and to be utilized for offices for medical practitioners and dentists.

Personal.—Dr. John H. Florence, state quarantine officer at Galveston, has resigned to become chief medical officer of the Great Southern Life Insurance Company, Houston.——Dr. Edward B. Parsons, Palestine, formerly physician of Anderson county, has been made county health officer.

New Laboratories.—Under the provisions of the thirty-fourth legislature, creating a state board of health, Dr. E. H. Lancaster, state bacteriologist, has fitted up in the state health department, Austin, a chemical and bacteriologic laboratory.——Dr. George W. Larendon, health officer of Houston, announces that the equipment for the new city laboratory is ready and that the laboratory will soon be opened. The bacteriologic department is to be under the direction of Dr. Felician J. S. Lataper.

College Matters.—The opening exercises of the Fort Worth Medical College were held September 27.——The work of the State University of Texas Medical Department, Galveston, began October 1. Under the new requirements, the applicant for matriculation must be a graduate of a high school, and next year a more severe requirement is to be exacted, that the student must have been engaged in one year's work at some recognized college or academic school. Dr. Harry O. Knight has succeeded Dr. Henry Hartman as demonstrator of pathology, and Dr. E. E. Calloway has succeeded Dr. H. T. Aynesworth as demonstrator of anatomy.

UTAH

Hospital Notes.—The Dee Memorial Hospital, in memory of the late Thomas Dee, is to be four stories in height, and will accommodate 85 patients.——Dr. Andy J. Stewart, Mount Pleasant, is preparing to build and equip a modern hospital at that place to fill a need long experienced for such an institution in southern Utah.

Personal.—Dr. Ross Anderson has resigned as professor of bacteriology and pathology in the University of Utah, and has been succeeded by Dr. Frank A. McC. Jenkin, Ann Arbor, Mich.——Dr. E. G. Hughes has succeeded Dr. James E. Hosmer, resigned, as city physician of Provo.——Drs. Julius L. Arntzen, Elsinore, and Thomas Ray Gledhill, Ruthfield, have been appointed quarantine physicians of Sevier county.

Declares Against Publicity.—The Utah County Medical Society, at a meeting held in Provo, September 9, adopted resolutions protesting against the publication of medical cases and naming the physicians connected therewith, and instructed the secretary to notify newspapers to this effect, and request reporters and papers to refrain from publishing names of physicians, places of operation, etc., without express permission from the attending physician.

GENERAL NEWS AND COMMENT

A Correction.—In The Journal, September 18, page 842, in the discussion on the Serodiagnosis of Syphilis, the remarks ascribed to Dr. Frank E. Fox, Fulton, N. Y., should have been accredited to Dr. Howard Fox, New York City.

Obstetricians and Gynecologists Elect Officers.—At the annual meeting of the American Association of Obstetricians and Gynecologists, held in Fort Wayne, Ind., September 21-23, the following officers were elected: President, Dr. Aaron B. Miller, Syracuse, N. Y.; first vice-president, Dr. Charles N. Smith, Toledo, O.; second vice-president, Dr. Raleigh R. Huggins, Pittsburg, Pa.; secretary, Dr. William Warren Potter, Buffalo (re-elected); and treasurer, Dr. Xavier O. Werder, Pittsburg, Pa. Syracuse was selected as the place and September 20, 21 and 22, 1910, as the time for holding the next annual meeting.

Public Health Association Meeting.—The preliminary announcement of the thirty-seventh annual meeting of the American Public Health Association to be held in Richmond, Va., October 19-22, under the presidency of Dr. Gardner T. Swarts, Providence, R. I., states that the Jefferson Hotel is to be the headquarters for all meetings; that a joint session of the Laboratory Section and Section of Municipal Health Officers is proposed, at which Drs. William H. Welch, Harvey W. Wiley and John S. Fulton have promised to read papers on the relation of laboratory work to executive work, and the problems which concern both executive and laboratory men, and their relations to each other. The Section of Municipal Health Officers proposes to take up the following subjects: Appointment and supervision of employees in the municipal sanitary service; the relation of the municipal health department to the city government generally, and to other branches of the city government; the control of the food supply; the prevention and abatement of nuisances; the prevention of the spread of communicable diseases of man; the prevention of the spread of communicable diseases of animals; the medical inspection of schools; the improvement of the physical condition of city dwellers; municipal vital statistics and municipal health laws.

LONDON LETTER

(From Our Regular Correspondent)

London, Sept. 18, 1909.

The Hospital Question

With the progress of medical science and the greater development of specialism there is an increasing tendency on the part of the public to seek hospital treatment. This is no doubt partly due to the fact that while competition has lowered the fees of general practitioners sometimes to such a low figure as to render proper treatment impossible or at any rate improbable, only the hastily prescribed stock mixture without proper examination being remunerative, on the other hand the fees of specialists have not only shown no tendency to fall but have actually risen. Some statistics which have recently been compiled show that there are 796 hospitals in the United Kingdom with a total income of $18,000,000. In addition there are 206 dispensaries with an income of $1,160,000, of institutions for the chronic and incurable there are 43, with an income of $1,190,000, and 242 institutions for the convalescent with an income of $1,750,000. Thus $22,000,000 is spent in the relief of the sick by institutions supported by the charitable, to say nothing of the poor-law infirmaries and fever hospitals which are supported by the state. The services of the physicians, which are given without payment (excepting some small salaries for house physicians and surgeons), do not enter into this total of expenditure. The profession is always bewailing the fact that it gives so much away, but there is always the keenest competition for these unpaid posts, because they are the only portal to the select class of consultants and specialists, who receive fees about twenty times as great as the average physician. It might fairly be argued that their services to the hospitals are not unremunerated but are paid by the enhanced fees of their rich patients; their interests are, therefore, in one sense diametrically opposed to those of the general practitioner. Their object is to get sufficient material experience to make a reputation in whatever line of work they take up and the question whether the patients could pay the small fees of the general practitioner does not concern them. However, there are many cases in which the patients could pay those fees but their case is a special and difficult one, requiring the skill of the specialist, whose much larger fees they could not pay. They are then legitimate cases for hospital treatment and indeed are often sent there by the general practitioner under these circumstances. From time to time the question of hospital abuse by those able to pay for medical advice is discussed by the British Medical Association and various other medical societies and resolutions are passed and recommendations made to hospital committees. But these committees consist of laymen, sometimes with a small sprinkling of the consultants on the hospital staff who are in little sympathy with the general practitioner. In some hospitals, however, a method has been adopted of stemming the torrent of abuse by appointing inquiry officers to investigate the financial position of those applying for relief by visits to their homes, etc.

Thief Discovered by a Thermometer Reading

The death of Dr. Whitelaw of Kirkintilloch, Scotland, has revived the following interesting story of his early career. Being called up one night many years ago he was walking with the messenger, when he was attacked and knocked down in a lonely road in the outskirts of Glasgow. His pockets were rifled and he was left lying in the road with a fracture of the fibula. One of the articles stolen was a clinical thermometer with which he had that evening taken the temperature of a patient suffering from typhoid fever. He remembered what the temperature registered and also that he had not shaken down the mercury before putting the thermometer back in his pocket and communicated these facts to the police. Some time afterward a thermometer registering the identical temperature was discovered in a pawn shop in Glasgow. By this means the police were enabled to track the doctor's assailants and to arrest them.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Sept. 10, 1909.

The Medical Record Book in the Marine Service

M. Henri Chéron, assistant secretary of the navy, has just decided on the issue of a medical record book for each man in the marine service, similar to one used in the army on land, in which will be entered the marine's height, weight, chest measurements and acuteness of visual and auditory perception. This book will follow the man wherever he goes. The military medical officers will set down there the results of their examinations, the names of the diseases treated, admissions to hospital, convalescence, etc. This book will permit the medical officers, whose task is particularly difficult because of the incessant changes to which the marine service is subject, to watch over and to treat their patients more easily. Moreover, the examination of this record book will be particularly useful at the time of reenlistment or reengagement, in order to avoid taking on men who are unfit for service. The medical record book will be passed from physician to physician, under sealed cover, and the disease treated, when of a confidential nature, will be indicated only by number. The injuries or accidents which might entitle the man to a pension will be very exactly described in this record.

Measures Against Cholera

About a year ago, in view of the epidemic of cholera which was raging in Russia, the French government put in force a series of preventive measures (THE JOURNAL, Oct. 10, 1908, lii, 1245). The terrible scourge has now entered Holland, where twenty-four cases were recorded during the first week of September. Therefore, a decree is about to be issued according to which a watch will be kept over all persons entering France by river or canal.

Fraudulent Assumption of the Doctor's Degree

All our political journals are filled with pseudoscientific articles which really are only advertisements of pharmaceutical products, signed by self-styled physicians.

The law of 1892 in regard to the practise of medicine took cognizance, indeed, of the fraudulent assumption of the doctor's degree, but it provided no punishment except in connection with the illegal practise of medicine, in which case the offense was aggravated and the penalty was greater. Illegal practise is punished by a fine of $20 to $100 (100 to 500 francs), and for a second offense, $100 to $200 (500 to 1,000 francs). Illegal practise with fraudulent assumption of the doctor's degree is punished by a fine of $200 to $400 (1,000 to 2,000 francs), and for the second offense, $400 to $600 (2,000 to 3,000 francs); moreover, the delinquent is subject to imprisonment of six months to a year. As proof of the practise of treating patients is necessary, according to our law, in order to constitute the offense of the illegal practise of medicine, the mere fact of assuming the doctor's degree in the daily papers or in pamphlets does not constitute a legally punishable offense. The Association of Medical Journalists (*Association des journalistes médicaux*) has repeatedly discussed the question of pretended doctors, and decided to recommend to the various scientific and journalistic associations action against the false assumption of degrees.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 15, 1909.

Campaign Against Proprietaries

The ever-increasing abuse of proprietary medicines has at last called forth protests from both physicians and the official apothecaries. Naturally, the government—the panacea in this country—has been expected to protect the interests of the public as well as those of the profession, but the expectation has not been fulfilled because of the powerful mercantile influences that are behind the proprietary medicine business. A resolution was recently passed at the regular meeting of the Silesian Medical Council (*Aerztekammer*) and forwarded to all "sister" councils in Austria for consideration, so that uniform action might be taken. The resolution aims to formulate some method by which the sale of proprietary medicines may be controlled. Two methods have been suggested. One is the proposal that a tax of 50 per cent. of the sale price of proprietaries shall be imposed on such medicines. The tax thus levied is to be devoted to public health purposes, etc. The chief objection to this plan is that practically the sale of such medicines would hardly be restricted, but the public would have to pay 50 per cent. more for its credulity. The second plan suggested and the one which has more probability of being carried, recommends that all proprietary medicines shall be sold only under the following conditions: They must not be advertised in any but medical periodicals. The labels and containers must have only the names of the articles and the names of their manufacturers or proprietors, and must not contain the names of any of the diseases for which the remedy is recommended. [This requirement is practically identical with Rule 4 of the Council on Pharmacy and Chemistry, which debars from admission to New and Nonofficial Remedies any article "whose label, package or circular accompanying the package, contains the names of diseases in the treatment of which the article is said to be indicated."—ED.] The manufacturers of proprietary medicines which contain potent drugs, may have to submit evidence regarding the composition and the claims made for these articles. The advantages of this second plan are so numerous that it is expected that it will be adopted.

The Winter Semester

The winter semester of the Vienna University begins officially with the first Monday in October, but some classes begin earlier, while the regular semestral classes do not start before the eighteenth. Amongst the new professors, whose lectures are looked forward to with eager interest, are those of the eye and the gynecologic clinics; they are not yet appointed, but the decision of the ministry of education is expected in October. A number of classes by serologists and pathologists dealing with the latest additions to modern serology are announced, otherwise the number of regular lectures is the same as usual. Including the classes by privat-docents and assistants, no less than 460 courses and classes will be held by the medical faculty of the Vienna University from October till March. The fee is generally from $10 to $25; the duration is from sixteen to twenty-four hours, except in regular semestral classes, lasting six months.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 8, 1909.

The Etiologic Significance of Spirochæta Pallida

After the significance of *Spirochæta pallida* as a cause of syphilis has been established apparently without dissent, there suddenly appears an article in the *Deutsche medizinische Wochenschrift* from the well-known bacteriologist, Schereschewsky, that is calculated to reopen the question. In his article, which is a reproduction of an address at the International Congress at Budapest, Schereschewsky communicates the results of further investigations which he has made on the culture of the *Spirochæta pallida* at Neisser's clinic at Breslau in pursuance of the work which he published a few months ago. He has succeeded in cultivating the spirochete, but he has not been able to infect animals with these cultures. In spite of an observation period of from one to four and a half months, none of his inoculations gave rise to an affection which could be regarded as syphilis. He meets the question of the significance to be attached to the unsuccessful animal inoculations by himself and others, by asserting a doubt whether the *Spirochæta pallida* is really the exciting cause of syphilis. We must not hesitate, he remarks, to subject to renewed criticism the relation of Schaudinn's spirochete to syphilis which was so readily accepted. It may be possible, indeed, that the spirochetes have lost their virulence by cultivation; such behavior, however, has never been observed in cultivated microorganisms. It might also be possible that the spirochetes cultivated by Schereschewsky in spite of their microscopic resemblance were not the genuine *Spirochæta pallida* which causes syphilis. It would be a severe criticism of the author to accept this explanation; he has hitherto believed that he was able to recognize the *Spirochætæ* in spite of their morphologic variability. If his skill in this respect is to be doubted it would be necessary to doubt the diagnostic significance of the finding of the *Spirochætæ* in general. There is no question that this article, which has been prepared by an experienced author under the supervision of Neisser, will attract the greatest attention.

Advent of Cholera

Cholera has now been introduced into Holland by sea, and 15 cases with 10 deaths have occurred at Rotterdam. There are 74 suspected persons under medical supervision. Undoubtedly, the cholera was introduced from Russia. In St. Petersburg, since the beginning of the present cholera epidemic, about 14,000 persons have been attacked, and 5,500 have died of the disease.

Pharmacology

[Contribution from the Chemical Laboratory of the American Medical Association]

ANUSOL HEMORRHOIDAL SUPPOSITORIES

W. A. Puckner and L. E. Warren

An abstract of an article concerning "anusol suppositories" was published in The Journal, Jan. 23, 1909. This gave the results of an analysis by a foreign chemist, J. F. Suyver, which were to the effect that "anusol suppositories" contained no "anusol." Schering & Glatz, the American agents for "anusol" suppositories, took exceptions to the abstract, asked that The Journal retract, and submitted the findings of a chemist in support of their claim that the suppositories do contain "anusol." To determine the composition of "anusol hemorrhoidal suppositories" as they are found on the American market, trade packages were purchased (April 6, 1909) and submitted to examination in the Association's laboratory.

According to the claims of the manufacturers, 12 suppositories contain:

"Anusoli	7.5 grams
"Zinc oxid	6.0 grams
"Balsam Peruv	1.5 grams
"Ol. theobrom	19.0 grams
"Ungt. cerat	2.5 grams"

Calculated to percentages the formula reads:

Anusoli	20.54 per cent.
Zinc oxid	16.44 per cent.
Balsam Peruv	4.11 per cent.
Ol. theobrom	52.06 per cent.
Ungt. cerat	6.85 per cent.

When this product was submitted to the Council some time ago, Schering & Glatz stated that, according to the manufacturer, "anusol" is the "iodo resorcin sulphonate of bismuth, having the following rational formula: $[C_6H_2ISO_2.O(OH)_2]_3Bi$. In the meta-dioxybenzol $C_6H_4(OH)_2$, the resorcin, one H has been replaced by one I, and for another H the sulfonic-acid group So_2-OH has been substituted, so that meta-dioxybenzol is transformed into $C_6H_2ISO_2\text{-}OH(OH)_2$. In the sulfonic acid the H of OH is replaced by Bi and, as Bi is trivalent the above rational formula results."

According to this formula "anusol" should contain:

Iodin	32.99 per cent.
Sulphur	8.34 per cent.
Bismuth	18.07 per cent.

And the "anusol" suppositories should contain:

Iodin	6.77 per cent.
Sulphur	1.71 per cent.
Bismuth	3.71 per cent.

Examination[1] showed that the suppositories contain about 0.08 per cent. iodin, or 1.2 per cent. of the amount claimed; 0.28 per cent. sulphur, or 16.3 per cent. of what is claimed; 0.71 per cent. bismuth, or 19 per cent of what is claimed; and zinc equivalent to 16.5 per cent. zinc oxid, or about 100 per cent. of claim.

From the standpoint of the iodin content alone, assuming that all of the iodin found is present in the form of "anusol," the results of the examination of the product (as found on the American market) verifies, for all practical purposes, Suyver's statement that "anusol suppositories contain no anusol," for the quantity of iodin present is so minute (about 1/82 of that required by the formula) as to be unworthy of serious consideration. The presence of sulphid in appreciable amounts was demonstrated showing that the sulphur is present, at least in part, in the form of sulphid and not as sulphonate as is claimed. In a measure, too, this is in accord with the findings of Suyver, who concluded that, in the product which he examined, the bismuth was present in the form of sulphid. The proportions of sulphur and of bismuth (respectively about 1/6 and 1/5 of the required amounts) indicate still further that the product is not all that it is claimed to be.

A specimen submitted by Schering & Glatz to the Council two years ago contained 0.09 per cent. iodin, or 1.3 per cent. of the amount claimed; 0.23 per cent. sulphur, or 13.4 per cent. of the claimed amount; and 0.52 per cent. bismuth, or 14 per cent. of what is claimed by the formula. Since the above determinations were made another specimen of Anusol Hemorrhoidal Suppositories was received from Schering & Glatz, July 16, 1909. This sample was found to contain about: 0.075 per cent. iodin, or 1.1 per cent. of the amount required by the formula; 0.265 per cent. of sulphur, or 15.5 per cent. of the requirement and 0.88 per cent. bismuth, or 23.7 per cent. of the required amount. It will thus be seen that the composition of the oldest specimen and also that of the specimen recently sent, corresponds in a general way with that of the one first examined.

Whether judgment be based on the determination of the bismuth, the sulphur or the iodin, the results just given clearly show that the claims made concerning the composition of "Anusol Hemorrhoidal Suppositories" are not substantiated by the facts.

Hayes Asthma Cure

To the Editor:—Kindly give me information concerning "The Hayes Method for Asthma and Hay Fever," concerning which I enclose a circular. E. Parrish, Brooklyn.

Answer.—The Hayes asthma remedies were analyzed in the pharmaceutical institute of the University of Berlin by J. Kochs, and, according to the *Arbeiten aus dem Pharmazeu-*

---

[1] Details of the quantitative analysis of "Anusol Hemorrhoidal Suppositories" will appear in the annual report of the Chemical Laboratory of the American Medical Association, or they may be had on request.

tischen Institut der Universität, Berlin, vol. iv, p. 122, with the following results. Six of the seven remedies were examined:

1 (Labeled No. 781).—A cough medicine for use in colds, catarrhs, bronchitis and for the relief of asthma. Dose 20 to 30 drops. This is said by the analyst to contain about 6.5 per cent. of oils, consisting chiefly of oils of turpentine and peppermint, emulsified and sweetened with syrup.

2 (Labeled T. I. Q.).—A remedy that is to be taken in doses of 15 minims three times a day before meals. According to the report, it contained 13.7 per cent. of iodin in the form of potassium iodid, to which had been added a little wine and a small percentage (0.1) of hydrochloric acid.

3 (Labeled No. 769 A.-C.).—A remedy to be given in doses of 30 minims at bedtime, to be repeated two or three times in several hours. This, says Kochs, was a slightly reddish syrup containing 6.7 per cent. of iodin combined as potassium, sodium and ammonium iodids.

4 (Labeled T. II Q.).—A preparation to be taken in doses of 15 minims three times a day immediately after meals. The analytical report shows it to contain 1.08 per cent. of iron in the form of an iron peptonate.

5 (Labeled No. 808).—These were small capsules filled with 0.1 gm. (1.5 grs.) of a loose white powder. It is said "to strengthen the lungs and reduce the tendency to taking cold." Analysis is said to have disclosed that it consisted of quinin sulphate.

6 (Labeled No. 763).—Small white sugar-coated pills. These are said to act mildly on the liver and regulate the digestion. The active principle of these pills as shown by the analysis was resin of jalap.

Correspondence

Expression of Cataract in Its Capsule

To the Editor:—The letter of Major Henry Smith, I. M. S., in The Journal, Sept. 11, 1909, needs an answer because of the bias of this "most interesting man in the world."

With all due deference to the great experience of Major Smith, which has never even been approached by any other operator, and to the details of the operation which he (Smith) claims as his own, yet I consider that a slightly larger incision than that described in the original essay of Pagenstecher in 1865, and small modifications claimed in the procedure should not take away the honor of priority of description and practice of the procedure from Pagenstecher and give the operation the name of Smith of Jullundur.

Indeed, as has been noted in Greene's and my papers, the same operation was done even before the time of Pagenstecher, although not generally practised. In Benjamin Bill's. "System of Surgery," reprinted in Boston in 1791, it is noted that a French oculist regularly operated in suitable cases by removing the lens in its capsule.

The expression operation is specifically described by Pagenstecher and Elschnig as follows:

> *Nach dem Drittelbogenschitt nach oben mit Bindehautlappen wird iridectomiert und hierauf die Linse, entweder durch das blosse Druckmanöver oder mit dem flachen Löffel der bloss als Gleitfläche dient, entbunden.*
>
> The lens is expelled after incision of about one-third of the circumference made with a conjunctival flap and an upward iridectomy either by means of gentle pressure or with the flat spoon acting purely as a gliding surface.

I have had occasion to look over my collection of so-called Pagenstecher spoons and among the seven which I possess find *only* one which in any way corresponds with the cup-shaped instrument depicted by Smith. The others all offer the gliding surface as described above.

Why then did I not quote Pagenstecher's writings on "Expression of Cataract in the Capsule" between 1888 and 1908? My position as editor of *Ophthalmology* and kindred publications for the past twenty years gives me rather an exceptional command of ophthalmic literature, yet I am not aware that there have been any such publications of his during this time!

The necessity for at least a 3/5 incision of the sclerocornea or a larger one when purely in the cornea has been pointed out by other writers besides Smith and myself. While I am favorable to the operation of expression of cataract in its capsule it is yet *sub judice,* and it must be proved that it is "the best operation in the world" by its ultimate results.

H. V. Würdemann, M.D., Seattle, Wash.

Tubercle Bacilli in the Blood—A Claim for Priority

To the Editor:—Referring to your editorial, "Tubercle Bacilli in the Blood," in The Journal of Sept. 18, 1909, I wish to call attention to the fact that in May, in a paper by Dr. Lyons and myself, which was read before the Louisiana State Society, in which we reported failure to confirm certain observations of Rosenberger, appears the following anent the presence of contaminating organisms in distilled water: "The danger of this occurrence is easily obviated by using water very recently distilled, or direct from the still, and by the thorough cleansing of the jars before using by means of a strong solution of mineral acid." As we were the first to report failure to confirm observations made by Rosenberger and encountering the error, corrected and reported on it, I believe that it should be credited to us and not to Brem. We went through the experiences which he reports in The Journal, in our paper directed attention to Rosenberger's faulty technic, and gave a method of overcoming the difficulty, and reported this some four months ago. I will thank you for giving this letter publication.

M. P. Burnham, M.D., Harrisonburg, Va.

Rhinology at the International Medical Congress

To the Editor:—The papers and discussions of the diseases of the accessory sinuses have been of special interest to rhinologists at the Sixteenth International Congress. Whereas, up to comparatively recent date, the pendulum had swung to ultraradicalism, at the congress it was evident that return had been made to safer measures. The authors of papers that were read and all of those who discussed the subject, with the single exception of Jansen, were strongly in favor of conservative measures except in extreme and rare cases. It was admitted that the radical operation did not usually result in quicker recovery than could be obtained from the less severe and more conservative operations. It was further admitted that these extreme operations were the cause of many deaths. About a dozen papers on these subjects were presented. Among those who read or discussed the papers were Dundas Grant (London), Uchermann (Christiania), Bourack (Charkoff), Jansen (Berlin), Killian (Freiberg), Chiari (Vienna), Massei (Naples), myself and several others whose names I do not now recall. Naturally great weight is given to the change of sentiment by the attitude of Killian, whose work along these lines is well-known. It is to be hoped that the preponderance of evidence brought out will result in placing the radical operation in its proper position, that is, an operation of the last resort.

E. Fletcher Ingals, Chicago.

Warning Against Book Agent

To the Editor:—At present there is traveling through the southern states, a man reported to us to be about 35 or 40 years of age, clean-shaven face, weighing 250 or 265 pounds, about 6 feet high.

He is calling on physicians and others offering to sell them forty books for $20, and to make them local agents for the Lippincott Publishing Co. So far as we know, there is no concern in this country of that name. After securing the $20 or $25, nothing more is heard of this agent, and as the complaints come to us we have reason to believe that he is working on our reputation. He has been working through Louisiana, Mississippi and Arkansas, and has used the names of Bradford, Howard and Hackett, with various initials.

Judging from the numerous complaints received, his operations are extensive and successful from his standpoint.

We are doing all we can to have the police notified, and the man apprehended, though, of course, we cannot *prosecute,* as we have not been injured or victimized.

J. B. Lippincott Co., Philadelphia.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CHRONIC CEREBRAL HYPEREMIA

To the Editor:—Please outline the treatment (dietetic, hygienic and medicinal) which has been found the most satisfactory for chronic cerebral hyperemia. The patient is a woman, aged 30, unmarried, and has been a sufferer for about seven years. Acute exacerbations have been noted during that period, varying from twice a week to once a month. They are usually preceded by nausea or vomiting, but not in every instance. Dietetic indiscretions have been interdicted and corrected. Refractive errors have been corrected. There is no malformation, lack of function or pathologic disturbance of the uterus or appendages. The patient is a worker on fine oriental rugs. While this may be to some extent a factor, it seems more probable that the disease was induced by extreme mental anxiety due to her father's financial misfortunes and subsequent death. The family history is good.

J. C. C., Philadelphia.

Answer.—Modern neurology does not recognize "chronic cerebral hyperemia" as a unique and separate disease. In the "chronic" form, congestion of the brain is always secondary to some other pathologic condition. The congestion may be active (arterial), or passive (venous); but in either case, physical obstruction to the circulation as from tumor, or disease of some sort of the vascular apparatus, is the real malady to be diagnosed and treated. There is no treatment for "chronic cerebral hyperemia" apart from the treatment of the underlying condition of which it is a secondary result. The symptoms that used to be attributed to cerebral hyperemia are now known to be due, when dependent on the intracranial circulation at all, to the quality of the blood and the speed of the current, rather than to the quantity. The anastomoses of the intracranial circulation are so abundant that cerebral hyperemia, except when it is secondary to, and a part of, some other pathologic state, is always a temporary affair. The treatment for temporary congestion of the brain is so well known as to need no special outline here.

The case noted above is not reported in sufficient detail to permit of a diagnosis. If further data can not be obtained from a thorough physical examination of the patient, "the extreme mental anxiety due to the father's financial misfortunes and his subsequent death," coupled with the fact that she "is a worker on fine oriental rugs" may legitimately awaken the suspicion of a psychoneurosis of the hystero-neurasthenic form. A further examination along this line, however, would be needed to establish the diagnosis. The hygienic, dietetic and medicinal treatment of a psychoneurotic patient, in whom there are hysterical and neurasthenic manifestations, is too large a subject for full consideration here; and its details depend on too many contingencies to permit of the formulation of a single scheme.

If the case is one of hysteria, the treatment should be preeminently along psychotherapeutic lines. Psychasthenia, unlike hysteria, is somewhat of a mental inefficiency. The treatment of hysteria, however, is more or less applicable to psychasthenia, with perhaps somewhat greater stress laid on rest, nutrition and a general tonic regimen. Neurasthenia, unlike hysteria and psychasthenia, calls most loudly for prolonged rest and increased nutrition. The entire course of the treatment of neurasthenia should occupy not less than six weeks. The hygiene of the patient, of course, should be of the best. Proper clothing, cleanliness, and regular habits are the requirements here. The dietetics involve no particular line of food; nutrition being the great desideratum, all foods that the patient can digest and assimilate should be tried and pushed to the limit of the physiologic powers of the alimentary organs. Water should be abundantly taken. A few simple tonics, such as iron, arsenic, strychnin, quinin, continued for a long period of time in very moderate dosage, conclude practically the medicinal treatment of nervous exhaustion.

In general practise most of the cases seen are hystero-neurasthenic. A hysterical woman exhausts her nervous mechanism; and a neurasthenic individual sooner or later develops a hysteroid state of mind. The treatment of these patients, therefore, calls for a combination of the methods briefly outlined above.

SOLUBILITY OF PHENOL (CARBOLIC ACID)

To the Editor:—In an editorial in The Journal (September 18, p. 954) in the discussion of tetanus appeared the statement to cauterize the wound with a "25 per cent. phenol solution." Evidently a 25 per cent. aqueous solution was to be understood. Statements are so frequently made by physicians about 25 per cent. and 50 per cent. solutions of phenol in water at ordinary room temperature that one is forced to think that some of them are not familiar with the solubility relations of water and phenol. The ease with which possibly serious burns might be produced makes a knowledge of these relations important. At ordinary room temperature (25 degrees C), if an attempt is made to obtain a 25 per cent. solution of phenol in water, two immiscible solutions will separate in two layers, the lower layer containing 75 per cent. phenol and the upper layer containing 7.5 per cent. phenol. A fairly thorough exposition of these solubility relations may be found in "The Phase Rule and Its Applications," by Alexander Findlay, on pages 95-8.

C. R., Kansas City, Mo.

Answer.—While the failure to state that the 25 per cent. solution of phenol should be "in glycerin or alcohol" was open to criticism, nevertheless, the facts regarding the solubility of this agent have been so often reiterated and its use is so common that details would seem to be scarcely necessary.

TECHNIC OF THE WASSERMANN TEST

To the Editor:—Please give reference to the best description of the technic of the Wassermann test in the medical literature of this country.

N. Evans, Nashville, Tenn.

Answer.—Good descriptions of the technic of the Wassermann test are given in the following:

Fleischmann, P. and Butler, W. J.: Serum Diagnosis of Syphilis, The Journal A. M. A., Sept. 14, 1907, xlix, 934.

Fox, H.: The Principles and Technic of the Wassermann Reaction and Its Modifications, *Med. Rec.*, March 13, 1909, lxxv, 421.

Reference may also be made to the following:

Castelli, E.: The Technic of the Wassermann Reaction, *New York Med. Jour.*, April 17, 1909, lxxxix, 777.

Butler, W. J.: Serodiagnosis of Syphilis, *New York Med. Jour.*, Jan. 30, 1909.

HEADACHE FOLLOWING ADMINISTRATION OF POTASSIUM IODID AND FOWLER'S SOLUTION

To the Editor:—All of our authorities teach that small doses of Fowler's solution will prevent the eruption so common in the administration of potassium iodid. In the past few years I have given it in small doses, but invariably my patients would suffer with an unbearable headache.

I have never seen this mentioned in any medical literature, and I would like some explanation. I am certain that the headache is not a mere coincidence.

J. J. Hardy, Poteau, Okla.

The Public Service

Medical Department of the Army

Changes for the week ended Sept. 25, 1909:

Kean, J. R., lieut. col., detailed to attend meeting of American Public Health Association at Richmond, Va., Oct. 19 to 22.

Murtagh, J. A., Van Poole, G. M., Reno, W. W., Gosman, G. H. R., Koerper, C. E., Allen, J. H., Patterson, R. U., Noble, R. E., Van Dusen, J. W., Grubbs, R. B., Sweazy, V. E., capts., ordered to report at Washington, D. C., for examination for promotion.

Truby, A. E., major, granted leave of absence for 1 month.

Brooks, W. H., Barney, C. N., McAndrew, P. H., De Witt, Wallace, [illegible] capts., ordered to report at San Francisco, for promotion.

[illegible] or, relieved from duty at the Presidio of San Francisco, Cal., and ordered to Fort D. A. Russel, Wyo., for duty.

Davis, A. D., 1st lieut., relieved from duty at Fort Lawton, Wash., and ordered to Vancouver Barracks, Wash., for duty.

Little, W. L., capt., ordered from Fort Adams, R. I., to Fort Ontario, N. Y., for temporary duty.

Dutcher, B. H., major, granted leave of absence for 15 days.

Wadhams, S. H., major, granted leave of absence for 4 months, when relieved at Fort Shafter, H. T.

Fuller, L. A., major, granted an extension of 1 month to his leave of absence.

Harris, H. S. T., lieut. col., ordered to assume temporary charge of medical supply depot, at San Francisco, Cal.

Craig, C. F., capt., relieved from duty as attending surgeon at New York City, and ordered to Washington, D. C., for duty as assistant curator, Army Medical Museum.

Artaud, F. E., Dougherty, J. C., Hughes, M. E., M. R. C., relieved from duty in the Philippines Division, and will sail December 15, for San Francisco, Cal.

Lemmon, Robt., Conzelmann, F. J., Watkins, V. E., M. R. C., relieved from duty at their present stations and will proceed to San Francisco to sail November 5, for Manila, P. I.

Kershner, W. E., M. R. C., ordered to active duty, and to proceed from Waterville, Me., to Fort Hancock, N. J., for duty.

Maloney, J. E., M. R. C., relieved from duty at Fort Hancock, N. J., and ordered to duty at Seattle, Wash., on the transport *Burnside*.

Lowe, T. S., M. R. C., relieved from duty on the transport *Burnside*, and ordered to duty at the Presidio of Monterey, Cal.

Wiggin, D. C., M. R. C., granted leave of absence for 1 month.

Heterick, R. H., M. R. C., ordered to active duty, and to proceed to Fort Oglethorpe, Ga., for duty.

Cohen, H. M., M. R. C., ordered to active duty, and to proceed to Fort Rodman, Mass., for duty.

Lyon, W. C., M. R. C., ordered to active duty, and to proceed to Fort Du Pont, Del., for duty.

Lavanture, L. A., M. R. C., ordered to active duty, and to proceed to Fort D. A. Russell, Wyo., for duty.

Hallett, H. J., M. R. C., ordered to active duty, and to proceed to Fort Totten, N. Y., for duty.

Sharpe, H. H., M. R. C., ordered to active duty, and to proceed to Fort Jay, N. Y., for duty.

Sherwood, J. W., M. R. C., ordered to active duty, and to proceed to Fort Williams, Me., for duty.

Dawe, C. W., M. R. C., ordered to active duty, and to proceed to Fort Thomas, Ky., for duty.

Miltenberger, V. E., M. R. C., ordered to active duty, and to proceed to Fort Riley, Kans., for duty.

Browne, R. W., M. R. C., ordered to active duty, and to proceed to Fort Monroe, Va., for duty.

Griffin, J. C., M. R. C., ordered to active duty, and to proceed to Fort Howard, Md., for duty.

Borden, W. R., M. R. C., ordered to active duty, and to proceed to Fort Bayard, N. M., for duty at the Army General Hospital.

Northington, E. G., M. R. C., ordered to active duty, and to proceed to Fort McPherson, Ga., for duty.

Hart, J. W., M. R. C., granted leave of absence for 2 months, at the expiration of which he will stand releved from active duty in the M. R. C.

Watkins, V. E., M. R. C., granted leave of absence for 15 days.

Jones, G. B., M. R. C., granted leave of absence for 1 month.

Medical Corps of the Navy

Changes for the week ended Sept. 25, 1909:

[illegible] surgeon, ordered to the Naval Recruiting [illegible] Tenn.

[illegible] argeon, commissioned surgeon from Oct. 11, 1909.

Fauntleroy, A. M., P. A. surgeon, ordered to the *Indiana*, and additional duty in connection with the *Lancaster*.

Reed, E. U., P. A. surgeon, detached from the Naval Recruiting Station, Nashville, Tenn., and ordered to Naval Hospital, Norfolk, Va., for duty.

Sutton, D. G., asst.-surgeon, detached from the *Vestal*, and ordered to the *Des Moines*.

Donelson, M., asst.-surgeon, detached from the Naval Recruiting Station, Chattanooga, Tenn., and ordered to the Naval Recruiting Station, Nashville, Tenn.

Flint, J., asst.-surgeon, detached from the Naval Hospital, Philadelphia, Pa., and ordered to the Naval Hospital, Navy Yard, Boston, Mass.

Crandall, R. P., surgeon, ordered to the *Hancock*.

Seaman, W., P. A. surgeon, ordered to the Naval Hospital, Navy Yard, New York.

The following Acting Assistant Surgeons have been detached from the places opposite their names and ordered to Instruction at the Naval Medical School, [illegible] 1909:

G. E. Robertson, detache [illegible] ass.
J. J. A. McMullin, detach [illegible] R. I.
J. T. Johnson, detached [illegible] Pa.
W. L. Irvine, detached [illegible]
H. E. Jenkins, detached Naval Hospital, Norfolk, Va.
D. C. [illegible] Norfolk, Va.
A. B. [illegible] York City.
W. H. [illegible] Norfolk, Va.
E. W. [illegible] New York City.
S. D. [illegible] v York City.
G. R. [illegible] Newport, R. I.
W. A. [illegible] School Hospital.
W. J. [illegible] arleston, S. C.
G. E. [illegible]
J. A. [illegible] Medical School, Washington, D. C.

Public Health and Marine-Hospital Service

List of changes for the seven days ended Sept. 22, 1909:

White, J. H., surgeon, granted 7 days, leave of absence from Sept. 18, 1909, under paragraph 189, Service Regulations.

Lavinder, C. H., P. A. surgeon, granted 3 days' leave of absence en route to station.

Goldberger, Joseph, P. A. surgeon, reassigned to duty in the Hygienic Laboratory, to date from Oct. 31, 1908.

Frost, W. H., P. A. surgeon, granted 1 day's leave of absence, Sept. 13, 1909, under paragraph 191, Service Regulations.

Warner, H. J., asst.-surgeon, granted 5 days' leave of absence from Sept. 25, 1909.

Browne, R. W., acting asst.-surgeon, granted 16 days' leave of absence from Sept. 16, 1909.

Burland, B. W., acting asst.-surgeon, granted 14 days' leave of absence from Sept. 13, 1909.

Curley, C. P., acting asst.-surgeon, granted 21 days' leave of absence from Sept. 25, 1909.

Duffy, Francis, acting asst.-surgeon, granted 3 days' leave of absence from Sept. 21, 1909.

Dynan, N. J., acting asst.-surgeon, granted 16 days' leave of absence from Sept. 13, 1909.

Light, S. D. W., acting asst.-surgeon, granted 30 days' leave of absence from Oct. 5, 1909.

Marsh, W. H., acting asst.-surgeon, granted 13 days' leave of absence from Oct. 2, 1909.

Mason, Wm. C., acting asst.-surgeon, granted 5 days' leave of absence from Oct. 4, 1909.

Robertson, Herman, acting asst.-surgeon, granted 14 days' leave of absence from Sept. 17, 1909.

Seavey, L. T., acting asst.-surgeon, granted 3 days' leave of absence from Sept. 15, 1909, under paragraph 210, Service Regulations.

Small, E. M., acting asst.-surgeon, granted 14 days' extension of annual leave on account of sickness from Aug. 30, 1909.

Thornton, M. J., acting asst.-surgeon, granted 13 days' leave of absence from Oct. 1, 1909.

Wetmore, W. O., acting asst.-surgeon, granted 1 day's extension of annual leave on account of sickness, Sept. 4, 1909.

Health Reports

The following have been reported to the Public Health and Marine-Hospital Service, during the week ended Sept. 24, 1909:

SMALLPOX—UNITED STATES

Illinois: Peoria, Aug. 1-31, 9 cases.
Indiana: Fort Wayne, Sept. 4-11, 3 cases.
Louisiana: New Orleans, Aug. 28-Sept. 4, 1 case.
Missouri: St. Louis, Sept. 4-11, 1 case.
Ohio: Dayton, Sept. 4-11, 5 cases.

SMALLPOX—INSULAR

Philippine Islands: Manila, July 24-31, 1 case.

SMALLPOX—FOREIGN

Brazil: Pernambuco, July 1-31, 27 deaths.
Chile: Valparaiso, Aug. 4-21, present.
China: Amoy, July 1-31, 9 cases, vicinity; Newchwang, July 31-Aug. 14, 2 cases, 1 death; Shanghai, July 31-Aug. 7, 1 death.
Ecuador: Ensenada, Aug. 10, epidemic; Guayaquil, July 1-31, 4 cases, 1 death, in vicinity.
France: Paris, Aug. 14-21, 1 death.
India: Calcutta, July 31-Aug. 7, 2 deaths; Rangoon, 2 deaths.
Italy: Naples, Aug. 22-29, 17 cases, 3 deaths.
Java: Batavia, July 31-Aug. 7, 1 case.
Mexico: Monterey, Aug. 29-Sept. 5, 1 death; Veracruz, 2 cases, 1 death.
Peru: Mollendo, Aug. 30, present.
Portugal: Lisbon, Aug. 21-28, 14 cases.
Russia: Moscow, Aug. 14-21, 3 cases, 2 deaths; Odessa, Aug. 7-21, 14 cases, 5 deaths; Riga, Aug. 21-28, 9 cases; St. Petersburg, Aug. 7-21, 40 cases, 11 deaths; Warsaw, July 10-17, 1 death.
Spain: Barcelona, Aug. 21-28, 6 deaths; Vigo, Aug. 14-28, present.
Turkey: Bagdad, July 17-Aug. 4, present.

YELLOW FEVER

Brazil: Manaos, July 7-14, 2 deaths; Para, Aug. 14-28, 9 cases, 9 deaths; Pernambuco, July 1-31, 2 deaths.
Ecuador: Guayaquil, Aug. 14-21, 3 deaths.
Mexico: Merida, Sept. 3-10, 2 deaths, in vicinity.
Venezuela: Maiquetia, Aug. 25, 1 case, vicinity of La Guaira.

CHOLERA—INSULAR

Philippine Islands: Manila, July 24-31, 1 case, 1 death; Provinces, July 24-Aug. 7, 278 cases, 191 deaths.

CHOLERA—FOREIGN

China: Amoy, July 31-Aug. 7, 15 deaths; Hankau, Aug. 3, present; Shanghai, Aug. 3-11, present.
India: Calcutta, July 31-Aug. 7, 7 deaths; Madras, Aug. 7-13, 1 death; Rangoon, July 31-Aug. 7, 3 deaths.
Manchuria: Dalny, Aug. 7-14, 1 case, on steamship Kobe Maru.
Netherlands: Amsterdam, Sept. 10, 1 case; Dirksland, 1 case; Middelburg, Aug. 28-Sept. 4, 1 case; Rotterdam, Aug. 20-Sept. 4, 34 cases, 14 deaths; Tholen, Aug. 28-Sept. 4, 1 case; Utrecht, 1 case; Vlaardingen, 1 case.
Russia: General, Aug. 21-28, 573 cases, 243 deaths; Moscow, Aug. 14-21, 1 case, 1 death; Riga, Aug. 21-28, 17 cases, 8 deaths; St. Petersburg, Aug. 22-29, 180 cases, 64 deaths.
Sweden: Stockholm, Aug. 12, 1 case, imported.

PLAGUE

Chile: Iquique, Aug. 22, 4 cases, in lazaretto.
China: Amoy, July 31-Aug. 7, 51 deaths; in Vicinity, July 1-31, 19 cases, 7 deaths; Hongkong, July 24-31, 2 cases, 2 deaths.
Ecuador: Guayaquil, Aug. 14-21, 5 deaths.
Egypt: General, July 29-Aug. 5, 9 cases, 2 deaths; Alexandria, Aug. 5, 1 case.
India: General, July 31-Aug. 7, 1,287 cases, 938 deaths; Calcutta, 15 deaths; Rangoon, 29 deaths.
Japan: Kobe, Sept 13, present.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arizona: Phœnix, October 4-5. Sec., Dr. Ancil Martin.
Colorado: Capitol, Denver, October 5. Sec., Dr. S. D. VanMeter, 1723 Tremont St.
Georgia: Regular, Capitol Bldg., Atlanta, October 12. Sec., Dr. E. R. Anthony, Griffin. Homeopathic: Atlanta, October 4. Sec., Dr. R. E. Hinman, 153 Whitehall St.
Idaho: Boise, October 5-6. Sec., Dr. W. F. Howard, Pocatello.
Illinois: Coliseum Annex, Chicago, October 20-22. Sec., Dr. J. A. Egan, Springfield.
Kansas: Topeka, October 12. Sec., Dr. F. P. Hatfield, Olathe.
Michigan: Lansing, October 12-14. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.
Minnesota: State University, October 5. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg., St. Paul.
Mississippi: Jackson, October 12. Sec., Dr. S. H. McLean.
Montana: Capitol, Helena, October 5. Sec., Dr. W. C. Riddell.
New Jersey: State House, Trenton, October 19-20. Sec., Dr. E. L. B. Godfrey, Camden.
New Mexico: Santa Fe, October 11-12. Sec., Dr. J. A. Massie.
North Dakota: Grand Forks, Oct. 5-7. Sec., Dr. H. M. Wheeler.
Oklahoma: Ione Hotel, Guthrie, October 13. Sec., Dr. Frank P. Davis, Enid.
Rhode Island: Room 313, State House, Providence, October 7-8. Sec., Dr. Gardner T. Swarts.
Utah: Room 207, City and County Bldg., Salt Lake City, October 4-5. Sec., Dr. G. F. Harding, 310 Templeton Bldg.
Wyoming: Laramie, October 20-22. Sec., Dr. S. B. Miller.

A Standard Medical Curriculum

At the Fifth Annual Conference of the Council on Medical Education, held in Chicago, April 5, 1909, a standard medical curriculum was recommended, the report of which is published in the *American Medical Association Bulletin*, September, 1909.[1] This supplies a long-felt need. Without a standard curriculum as a guide there would be danger that, instead of securing a fairly uniform curriculum, some colleges might lay too much stress on some subjects and too little on others, or might overload the curriculum with unimportant subjects and details. It was essential to arrange a medical curriculum which would not be so overcrowded as to prevent the best work but which would furnish the best training and equipment for practitioners in medicine. The domain of medical knowledge has become so extensive that it was quite necessary to point out what subjects should be required, how much emphasis should be laid on each and what subjects should be made elective.

---

[1] A copy of the Bulletin will be sent on receipt of four cents *for postage*.

In order to prepare this standard curriculum, the Council on Medical Education selected a Committee of One Hundred from the leading medical educators of the United States and Canada to make an exhaustive study of the problem. The subjects of the medical curriculum were arranged in ten groups and a subcommittee of ten members was selected for each group. Before active work was begun an outline was prepared giving the main propositions on which the curriculum was to be constructed. These propositions were: 1. The entire medical course was to cover four years of *at least* thirty weeks each, exclusive of holidays, consisting of thirty hours per week of actual work. 2. A four-year high-school education and in addition at least one year of college work devoted to courses in physics, chemistry, biology and modern languages was to be required for admission. 3. The total requirement in all branches of the medical curriculum for the four years was to be *at least* 3,600 hours. (The 4,100 hours of the curriculum recommended represents, therefore, the *maximum* requirement). Each member was forwarned that the chief difficulty would be the fixing of the number of hours to be devoted to each subject since the claims of all other subjects would have to be kept in mind.

In order to secure some uniformity of procedure a suggestive outline of the points to be taken up was prepared and specific recommendations were asked regarding: (a) prerequisite courses, referring either to preliminary requirements or to medical courses which should precede the subjects under consideration; (b) the place in the curriculum, whether in first, second, third or fourth year; (c) portions of the subject to be required and portions to be optional; (d) necessary qualifications of instructors; (e) the best methods of instruction; (f) the necessary laboratory equipment (apparatus), or, if a clinical branch, the minimum number of hospital or dispensary patients which should be required; (g) auxiliary facilities (library, museum, charts, stereopticons, reflectoscopes, etc.) which should be required; (h) the proportions of didactic (lectures or recitations) and practical (laboratory or clinical) teaching; (i) the minimum total of hours of a 3,600-hour curriculum to be devoted to the subject or subjects of each section. It was made clear that the outline was not intended to limit the discussions to the items mentioned but that specific recommendations relating to any other subjects or to the curriculum as a whole would be strictly in order.

It is stated by the Council on Medical Education that this standard curriculum is advanced for its educational value and not with the idea that all colleges should be required to conform strictly to it. In fact, absolute uniformity of curricula in all colleges is not desirable, although comparative uniformity will be of much benefit in permitting students more freedom to migrate from one college to another and in facilitating a larger interstate reciprocity in the licensing of physicians.

The ten divisions of the curriculum and the subcommittee assigned to each are as follows:

SECTION 1.—ANATOMY, INCLUDING HISTOLOGY AND EMBRYOLOGY

Chairman: Charles R. Bardeen, M.D., Professor of Anatomy, University of Wisconsin, College of Medicine, Madison, Wis.

Albert C. Eycleshymer, Ph.D., Professor and Director of the Department of Anatomy, Histology and Embryology, St. Louis University, Grand Ave. and Carolina St., St. Louis.

Irving Hardesty, Ph.D., Assistant Professor of Anatomy, University of California, Medical Department, San Francisco.

G. Carl Huber, M.D., Professor of Histology and Embryology, University of Michigan, College of Medicine, 1330 Hill St., Ann Arbor, Mich.

George S. Huntington, M.D., Professor of Anatomy, Columbia University, 437 W. 59th St., New York City.

Clarence M. Jackson, M.D., Professor of Anatomy and Histology, University of Missouri, Medical Department, Columbia.

Thomas G. Lee, M.D., Professor of Histology and Embryology, University of Minnesota, College of Medicine and Surgery, 509 St. Anthony Parkway, S.E., Minneapolis.

Franklin P. Mall, M.D., Professor of Anatomy, Johns Hopkins University Medical Department, 1514 Bottom St., Baltimore.

James P. McMurrich, Ph.D., Professor of Anatomy, University of Toronto, Medical Department, 576 Huron St., *Toronto, Canada.*

George A. Piersol, M.D., Professor of Anatomy, University of *Pennsylvania, Department* of Medicine, 4724 Chester Ave., Philadelphia.

SECTION 2—ORGANIC CHEMISTRY, PHYSIOLOGY AND PHYSIOLOGIC CHEMISTRY

[illegible] Lyon, Ph.D., Professor of Physiology, St. [illegible] [illegible]ool of *Medicine, St. Louis.*

[illegible], M.D., Associate Professor of Physiology, Johns Hopkins University, Medical Department, *Baltimore.*

Otto Folin, Ph.D., Professor of *Biologic Chemistry, Harvard* Medical School, Longwood Ave., Boston.

Walter E. Garrey, Ph.D., Professor of Physiologic Chemistry, Cooper Medical College, San Francisco.

Winfield Scott Hall, M.D., Professor of *Physiology, Northwestern* University Medical School, 2431 Dearborn St., Chicago.

Frederic S. Lee, Ph.D., Professor of *Physiology, Columbia University*, College of Physicians and Surgeons, New York City.

Warren P. Lombard, M.D., Professor of Physiology, University of Michigan, College of Medicine, 805 *Oxford Road*, Ann Arbor, Mich.

Graham Lusk, Ph.D., Professor of Physiology, Cornell University *Medical* College, 338 E. 26th St., New York City.

Gustav Mann, M.D., Professor of Physiologic Chemistry, Tulane University of Louisiana, New Orleans.

Albert P. Mathews, Ph.D., Professor of Physiologic Chemistry, University of Chicago.

SECTION 3.—PATHOLOGY AND BACTERIOLOGY

Chairman: William T. Councilman, M.D., Professor of Pathology, Harvard Medical School, 240 Longwood Ave., Boston.

J. G. Adami, M.D., Professor of Pathology, McGill University, Medical Department, Montreal, Canada.

W. M. L. Coplin, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College, Tenth and Walnut Sts., Philadelphia.

Harold C. Ernst, M.D., Professor of Bacteriology, Harvard Medical School, 240 Longwood Ave., Boston.

James Ewing, M.D., Professor of Pathology, Cornell University Medical College, 256 W. 57th St., New York City.

Ludwig Hektoen, M.D., Professor and Head of the Department of Pathology, Rush Medical College, 5803 Washington Ave., Hyde *Park, Chicago.*

William T. Howard, M.D., Professor of Pathology, Pathological Anatomy and Bacteriology, Western Reserve University, 1838 E. 65th St., Cleveland, Ohio.

Richard M. Pearce, M.D., Professor of Pathology and Bacteriology, University and Bellevue Hospital Medical College, 338 East 26th St., New York City.

Alfred S. Warthin, M.D., Professor of Pathology, University of Michigan, College of Medicine and Surgery, 924 Baldwin Ave., Ann Arbor, Mich.

William H. Welch, M.D., Baxley Professor of Pathology, Johns Hopkins Medical School, 807 St. Paul St., Baltimore.

SECTION 4.—PHARMACOLOGY, TOXICOLOGY AND THERAPEUTICS

Chairman: Torai[illegible] Professor of Pharmacology and Materia Medic[illegible] [illegible]ratory, Western Reserve University Medical [illegible] Ohio.

John J. Abel, M.D., Professor of Pharmacology, Johns Hopkins University Medical School, Charles St. Ave. (P. O. Sta. L.), Baltimore.

Joseph A. Capps, M.D., Assistant Professor of Medicine, Rush Medical [illegible] Chicago, 100 State St., Chicago.

David [illegible] [illegible]istant Professor of Medicine, University of [illegible] Department, 1432 Pine St., Philadelphia.

Charles Wallis Edmunds, M.D., Junior Professor of Therapeutics and Materia Medica, University of Michigan, College of Medicine, 520 East Ann St., Ann Arbor, Mich.

John Taylor Halsey, M.D., Professor of Materia Medica, Therapeutics and Clinical Medicine, Tulane University of Louisiana, 124 *Baronne* St., New Orleans.

Egbert LeFevre, M.D., Professor of Therapeutics and Clinical Medicine, University and Bellevue Hospital Medical College, 52 West 56th St., New York City.

Eli H. Long, M.D., Professor of Materia Medica and Therapeutics, University of Buffalo, Medical Department, Buffalo, N. Y.

William De Berneire MacNider, M.D., Professor of Pharmacology and Bacteriology, University of North Carolina, Chapel Hill.

Oliver Thomas Osborne, M.D., Professor of Materia Medica and Therapeutics and Clinical Professor of Medicine, Yale Medical School, 252 York St., New Haven, Conn.

SECTION 5.—MEDICINE, INCLUDING PEDIATRICS AND NERVOUS AND MENTAL DISEASES

Chairman: George Dock, M.D., Professor of Medicine, Tulane University of Louisiana, 124 Baronne St., New Orleans.

George Blumer, M.D., Professor of the Theory and Practic[illegible] of Medicine, Yale Medical School, New Haven, Conn.

William Fitch Cheney, M.D., Professor of Principles and Practice of Medicine, Cooper Medical College, Shreve Bldg., San Francisco.

Henry A. Christian, M.D., Professor of the Theory and Practice of Physic, Harvard Medical School, 252 Marlboro St., Boston.

F. X. Dercum, M.D., Professor of Nervous and Mental Diseases, Jefferson Medical College, 1719 Walnut St., Philadelphia.

Frederick Forchheimer, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio, Cincinnati.

Charles L. Greene, M.D., Professor of Medicine, University of Minnesota, College of Medicine and Surgery, Minneapolis.

L. Emmett Holt, M.D., Carpentier Professor of the Diseases of Children, Columbia University, College of Physicians and Surgeons, 14 W. 55th St., New York City.

John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania, Medical Department, Philadelphia.

W. Gilman Thompson, M.D., Professor of Medicine, Cornell University, Medical College, 34 E. 31st St., New York City.

SECTION 6.—SURGERY; GENERAL AND SPECIAL

Chairman: Charles H. Frazier, M.D., Professor of Clinical Surgery, University of Pennsylvania, Department of Medicine, 1724 Spruce St., Philadelphia.

Dudley Peter Allen, M.D., Professor of the Theory and Practice of Surgery and Clinical Surgery, Western Reserve University, Medical Department, 1110 Euclid Ave., Cleveland, Ohio.

Joseph A. Blake, M.D., Professor of Surgery, Columbia University, College of Physicians and Surgeons, 601 Madison Ave., New York City.

Herbert L. Burrell, M.D., Professor of Clinical Surgery, Harvard Medical School, 22 Newbury St., Boston.

Frederick Henry Gerrish, M.D., Professor of Surgery, Medical School of Maine, 675 Congress St., Portland, Me.

William S. Halsted, M.D., Professor of Surgery, Johns Hopkins University, Medical School, Baltimore.

Rudolph Matas, M.D., Professor of General and Clinical Surgery, Tulane University of Louisiana, 2255 St. Charles Ave., New Orleans.

Lewis S. McMurtry, M.D., Professor of Abdominal Surgery and [illegible] of Louisville, Medical Department, The [illegible] Chestnut Sts., Louisville, Ky.

[illegible] M.D., Professor of the Principles of Surgery [illegible] Medico-Chirurgical College, 1904 Chestnut St., Philadelphia.

Harry M. Sherman, M.D., Professor of the Principles and Practice of Surgery, University of California, Medical Department, 2210 Jackson St., San Francisco.

SECTION 7.—OBSTETRICS AND GYNECOLOGY

Chairman: Joseph B. DeLee, M.D., Professor of Obstetrics, Northwestern University Medical School, 810-34 Washington St., Chicago.

John G. Clark, M.D., Professor of Gynecology, University of Pennsylvania, Department of Medicine, 2017 Walnut St., Philadelphia.

Edwin B. Cragin, M.D., Professor of Obstetrics and Gynecology, Columbia University College of P. and S., 10 W. 50th St., New York City.

J. Clifton Edgar, M.D., Professor of Obstetrics, Cornell University Medical College, 28 West 56th St., New York City.

Charles M. Green, M.D., Professor of Obstetrics, Harvard Medical School, 78 Marlborough St., Boston.

James R. Guthrie, M.D., Professor of Obstetrics and Gynecology, State University of Iowa, Medical Department, 1005 Locust St., Dubuque, Iowa.

Ernest S. Lewis, M.D., Professor of Obstetrics and Gynecology, Tulane University of Louisiana, 124 Baronne St., New Orleans.

Reuben Peterson, M.D., Professor of Obstetrics and Gynecology, University of Michigan, Department of Medicine and Surgery, 620 Forest Ave., Ann Arbor, Mich.

[illegible] Professor of Obstetrics and Gynecology, [illegible] ouis.

[illegible] bstetrics, Johns [illegible] St., Baltimore.

SECTION 8.—DISEASES OF THE EYE, EAR, NOSE AND THROAT

Chairman: George E. deSchweinitz, M.D., Professor of Ophthalmology, University of Pennsylvania, Department of Medicine, 1705 Walnut St., Philadelphia.

Diseases of the Eye

Edward Jackson, [illegible] of Colorado, School [illegible]

Myles Standish, [illegible] Harvard Medical Sch[illegible]

William H. Wilde[illegible] d of the Department of Ophthalmol[illegible] 103 State St., Chicago.

Diseases of the Ear

Clarence John Blake, M.D., Professor of Otology, Harvard Medical School, 226 Marlboro St., Boston.

B. Alexander Randall, M.D., Clinical Professor of Diseases of the Ear, University of Pennsylvania, Department of Medicine, 1717 Locust St., Philadelphia.

Frank C. Todd, M.D., Professor of Ophthalmology and Otology, University of Minnesota, College of Medicine, 304 Pillsbury Bldg., Minneapolis.

Diseases of the Nose and Throat

Cornelius G. Coakley, M.D., Professor of Laryngology, University and Bellevue Hospital Medical College, 53 W. 56th St., New York City.

D. Braden Kyle, M.D., Professor of Laryngology, Jefferson Medical College, 1517 Walnut St., Philadelphia.

John N. MacKenzie, M.D., Clinical Professor of Laryngology and Rhinology, Johns Hopkins Medical School, 870 Park Ave., Baltimore.

SECTION 9.—DERMATOLOGY AND VENEREAL DISEASES

Chairman: William A. Pusey, M.D., Professor of Dermatology and Clinical Dermatology, College of Physicians and Surgeons, 72 Madison St., Chicago.

John T. Bowen, M.D., Edward Wigglesworth Professor of Dermatology, Harvard Medical School, 14 Marlboro St., Boston.

William T. Corlett, M.D., Professor of Dermatology and Syphilology, Western Reserve University, Medical Department, 1935 Euclid Ave., Cleveland, Ohio.

Isadore Dyer, M.D., Professor of the Diseases of the Skin, Tulane University of Louisiana, New Orleans.

John A. Fordyce, M.D., Professor of Dermatology, University and Bellevue Hospital Medical College, 80 W. 40th St., New York City.

T. Casper Gilchrist, M.D., Clinical Professor of Dermatology, Johns Hopkins University Medical Department, 330 N. Charles St., Baltimore.

William A Hardaway, M.D., Professor of Diseases of the Skin and Syphilis, Washington University, Medical Department, 4500 Olive St., St Louis.

Milton B. Hartzell, M.D., Associate in Dermatology, University of Pennsylvania, Department of Medicine, 3644 Chestnut St., Philadelphia.

Douglass W. Montgomery, M.D., Professor of Diseases of the Skin, University of California, Medical Department, 2419 California St., San Francisco.

Grover W. Wende, M.D., Clinical Professor of Dermatology, University of Buffalo, Department of Medicine, 471 Delaware Ave., Buffalo, N. Y.

SECTION 10.—HYGIENE, MEDICAL JURISPRUDENCE AND MEDICAL ECONOMICS

Chairman: F. F. Wesbrook, M.D., Professor of Pathology and Bacteriology, University of Minnesota, College of Medicine, Minneapolis.

Charles V. Chapin, M.D., Superintendent of Health, Providence, R. I.

Irving Fisher, Ph.D., Professor of Political Economy, Yale University, 460 Prospect St., New Haven, Conn.

John S. Fulton, M.D., Secretary-General, Sixth International Congress on Tuberculosis, 714 Colorado Bldg., Washington, D. C.

J. N. McCormack, M.D., Secretary Kentucky State Board of Health, Bowling Green, Ky.

C. O. Probst, M.D., Secretary Ohio State Board of Health, Columbus, Ohio.

M. P. Ravenel, M.D., Professor of Bacteriology, University of Wisconsin, Madison, Wis.

Franklin C. Robinson, A.M., Professor of Chemistry, Mineralogy and Natural Science, Bowdoin College, 214 Maine St., Brunswick, Me.

M. J. Rosenau, M.D., U. S. Public Health and Marine-Hospital Service, Washington, D. C.

Victor C. Vaughan, M.D., Professor of Hygiene and Physiologic Chemistry, University of Michigan, College of Medicine, Ann Arbor, Mich.

COLLABORATORS

Besides the regular members of the subcommittees there was a number of collaborators, or corresponding members to whom credit is due for many suggestions and much valuable assistance. These are as follows:

ANATOMY

Burton D. Meyers, M.D., Professor of Anatomy, Indiana University School of Medicine, Bloomington.

Arthur William Meyer, M.D., Professor of Anatomy, Northwestern University Medical School, Chicago.

Robert Bennet Bean, M.D., Associate Professor of Anatomy, Philippine Medical School, Manila, P. I.

Irving S. Haynes, M.D., Professor of Practical Anatomy, Cornell University Medical College, New York City.

PHARMACOLOGY, TOXICOLOGY AND THERAPEUTICS

E. D. Brown, M.D., Acting Professor of Materia Medica and Pharmacology, University of Minnesota, College of Medicine, Minneapolis.

[illegible] Bureau of Animal Industry, U. S. Dept. of [illegible]

[illegible] Professor of Pharmacology, University of London, England.

William J. Gies, Ph.D., Professor of Biological Chemistry, Columbia University, College of Physicians and Surgeons, New York City.

Charles W. Greene, Ph.D., Professor of Physiology and Pharmacology, University of Missouri, Medical Department, Columbia.

Herbert A. Hare, M.D., Professor of Materia Medica and Therapeutics, Jefferson Medical College, Philadelphia.

Robert A. Hatcher, M.D., Profess[illegible] Materia Medica, Cornell University Med[illegible] City.

Velyien Ew[illegible] and Pharmacology, [illegible] tario.

Christian [illegible] of Pharmacology and Therapeutics, C[illegible] of Physicians and Surgeons, New York City.

George Howard Hoxie, M.D., Professor of Internal Medicine, University of Kansas School of Medicine, 317 Argyle Bldg., Kansas City, Mo.

Reid Hunt, M.D., Hygienic Laboratory, Public Health and Marine-Hospital Service, Washington, D. C.

Samuel W. Lamber[illegible] [illegible] Applied Therapeutics, Columbia University, [illegible] and Surgeons, New York City.

A. S. Loevenhart, M.D., Professor of Pharmacology, University of Wisconsin, College of Medicine, Madison.

Samuel A. Matthews, M.D., Assistant Professor of Experimental Therapeutics, Rush Medical College, Chicago.

Samuel J. Meltzer, M.D., Rockefeller Institute, New York City.

Murray Galt Motter, M.D., Hygienic Laboratory, 25th and E St[illegible]

[illegible] rofessor of Pharmacology and Therapeutics, H[illegible] Longwood Ave., Boston.

Alfred M. Richards, Ph. D., Professor of Pharmacology, Northwestern University Medical School, 2431 Dearborn St., Chicago.

John G. Spenzer, M.D., Professor of General and Medical Chemistry and Pharmacology, Cleveland College of Physicians and Surgeons, Cleveland.

George B. Wallace, M.D., Professor of Pharmacology, University and Bellevue Hospital Medical College, New York City.

OBSTETRICS AND GYNECOLOGY

Howard A. Kelly, M.D., Professor of Gynecology, Johns Hopkins University, Medical Department, Baltimore.

Barton C. Hirst, M.D., Professor of Obstetrics, University of Pennsylvania, Philadelphia.

Emilius Clark Dudley, M.D., Professor of Gynecology, Northwestern University Medical School, Chicago.

Thomas J. Watkins, M.D., Clinical Professor of Gynecology, Northwestern University Medical School, Chicago.

Charles S. Bacon, M.D., Professor of Obstetrics, College of Physicians and Surgeons, Chicago.

William Robert Whities, M.D., Professor of Obstetrics, State University of Iowa, College of Medicine, Iowa City.

HYGIENE, MEDICAL JURISPRUDENCE AND MEDICAL ECONOMICS

Alexander Crever Abbott, M.D., Professor of Hygiene and Bacteriology, University of Pennsylvania Medical Department and Chief of the Bureau of Health, Philadelphia.

J. George Adami, M.D., Professor of Pathology, McGill University, and Consulting Bacteriologist of the Quebec Provincial Board of Health, Montreal.

John Andrew Amyot, M.D., Director of the Provincial Board of Health Laboratories of Ontario and Associate Professor of Pathology and Bacteriology, University of Toronto.

Henry Martyn Bracken, M.D., Secretary and Executive Officer of the Minnesota State Board of Health and Professor of Preventive Medicine, University of Minnesota, Minneapolis.

George W. Fuller, Hydraulic and Sanitary Engineer, New York City.

Allen Hazen, Hydraulic and Sanitary Engineer, New York City.

Hibbert W. Hill, M.D., Assistant Director Minnesota State Board of Health Laboratories and Assistant Professor of Bacteriology, University of Minnesota, Minneapolis.

William Travis Howard, M.D., Pro[illegible] [illegible]hological Anatomy and Bacteriology, Wes[illegible] and Director of the City Board of Health [illegible]

John N. Hurty, M.D., Secretary [illegible] f the Indiana State Board of Health, Indianapolis.

Thomas G. Lee, M.D., Professor of Histology and Embryology, University of Minnesota, Minneapolis.

William H. Park, M.D., Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, and Director of the Research Laboratories of the New York City Board of Health.

Herbert D. Pease, M.D., Director of the New York State Department of Health Laboratories, Albany.

Robert Spurr Weston, Sanitary Engineer, Boston.

George C. Whipple, Sanitary Engineer, New York City.

Iowa June Report

Dr. Louis A. Thomas, secretary of the Iowa State Board of Medical Examiners, reports the written examinations held at Des Moines, June 1-3 and 22-23, 1909, and at Iowa City, June 9-11, 1909. The number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 99, of whom 92 passed and 7 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
[illegible] iversity	(1908)	79.5
[illegible] Medical School	(1906) 88.7; (1907) 84; [illegible]	77.9, 83.1.
Hahnemann Medical College and Hospital	(1907) 75.4; (1908) 83.1; (1909)	84.5.
College of Physicians and Surgeons, Chicago	(1909)	84.1, 85.1, 86.4, 88.2.
Rush Medical College	(1905) 90; (1906)	90.1
Drake University	(1909)	75, 79.4, 79.7, 80, 81.5, 82.7, 83.6, 83.7, 84.9, 85.5, 86, 86.2, 87.9, 88.7, 89.4, 89.6, 89.7, 90.2.
University of Iowa, College of Medicine	(1909)	77.9, 80.6, 81, 82.1, 82.2, 82.2, 83.6, 83.7, 83.7, 84, 84.1, 84.2, 84.5, 84.5, 84.7, 84.9, 85, 85.2, 85.4, 85.4, 85.5, 85.9, 86.2, 86.4, 86.6, 86.4, 86.9, 86.9, 87, 87.1, 87.2, 87.4, 87.4, 87.7, 88, 89, 89.4, 90, 90.6, 91, 92.4, 92.6.
University of Iowa, College of Homeopathic Medicine	(1909)	86.5, 86.9, 89.5.
Sioux City College of Medicine	(1909)	75.2, 76.9
Johns Hopkins University	(1909)	81.6, 84.1
St. Louis College of Physicians and Surgeons	(1909)	76.5, 78.
Washington University, St. Louis	(1894)	76.7
University of Missouri	(1909)	82.5
University Medical College, Kansas City	(1909)	76.9
Creighton Medical College	(1909)	86.7
Ohio Medical University	(1896)	84.2
Jefferson Medical College	(1909)	90.1
Wisconsin College of Physicians and Surgeons	(1909)	80.2
Marquette University, Milwaukee	(1909)	77.4

FAILED

College	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1909)	69.2
Keokuk Medical College	(1900)	65.4
Keokuk Medical College, College of Physicians and Surgeons,	(1901) 65.7;* (1906)	66.7.†

University of Iowa	(1906)	67.6**
St Louis College of Physicians and Surgeons	(1909)	53.1

* Second examination. ** Third examination. † Fourth examination.

Marriages

William Edgar Lower, M.D., Cleveland, Ohio, to Miss Mabell Loring Freeman of Worcester, Mass., September 14.

Gideon Harmer Patton, M.D., Philadelphia, to Miss Martha Emerick of Harrisburg, Pa., at Philadelphia, September 15.

Charles Walter Waddell, M.D., Fairmont, W. Va., to Miss Myrtle DeVene Shaw Hoult, of Baltimore, September 14.

Guy Luvergne Bliss, M.D., Three Rivers, Mich., to Miss Edith Gertrude Smith, of Oskaloosa, Iowa, September 1[illegible]

Emil Francis Tholen, M.D., Tropico, Cal., to Miss Mary Sydney Shephard of Fort Madison, Iowa, September 15.

George Stanberry Walker, M.D., to Miss Mabel Robinson, both of DeLand, Ill., at Bloomington, Ill., September 15.

James B. Padgham, M.D., Donahue, Iowa, to Miss Ida Louise Battey of West Liberty, Iowa, September 8.

Francis Albert Brugman, M.D., Minot, N. D., to Miss Mabel V. Shalla of Iowa City, Iowa, September 15.

Edward Carlon Ferguson, M.D., to Miss Etta Louise Schwartz, both of Edwardsville, Ill., September 7.

William Frederick Zierath, M.D., to Miss Lydia Clair Hoehle, both of Sheboygan, Wis., September 17.

Gustavus Charles Dohme, M.D., Baltimore, Md., to Miss Ada Frances Chinn, at Baltimore, September 15.

E. Carlton Foster, M.D., Penn Yan, N. Y., to Miss Pearl A. Wixom of Hammondsport, N. Y., September 9.

John W. Sneed, M.D., Brentwood, Tenn., to Miss Margaret Williams of Nashville, Tenn., September 15.

J. Burton Rutherford, M.D., to Miss Bessie H. Shipley, both of Wilmington, Del., September 20.

Wibb Earl Cooper, M.D., U. S. Army, to Miss Pearl Herron of Nashville, Tenn., September 15.

Lewis Carthrae, Jr., M.D., Corder, Mo., to Miss Ella Mallonee of St. Louis, September 1.

Elijah C. Trout, M.D., to Miss Vernice L. Petty, both of Birds, Ill., September 8.

Deaths

William Christopher Krauss, M.D. Bellevue Hospital Medical College, New York City, 1886; University of Berlin, Germany, 1888; of Buffalo, N. Y.; a member of the American Medical Assotion and American Neurological Association; a member of the board of managers of the Buffalo State Hospital; medical superintendent of the Providence Retreat for the Insane; consulting neurologist to the Buffalo General, Erie County, German Deaconess, Emergency and Woman's hospitals, and the Buffalo Eye and Ear Infirmary; one of the editors of the *Buffalo Medical Journal*; an alienist and neurologist of repute; author of a work on syringomyelia and other spinal cord tumors; and translator of Mendel's work on "Psychiatry, a Study of Insanity," died suddenly in the New York Hospital, September 21, from nervous breakdown, aged 45.

Thomas Hovey Gage, M.D. Harvard Medical School, Boston, 1852; medical director and vice-president of the State Mutual Life Assurance Company, Worcester, Mass.; an original trustee of Washburn Memorial Hospital; a trustee and treasurer of Clark University; president of the Massachusetts Medical Society from 1886 to 1888; a member of the American Antiquarian Society; in charge of the hospital ship *Knickerbocker* during the Civil War; for many years a member and president of the board of trustees of the Worcester City Hospital; died at his home, September 17, from heart disease, aged 83.

George Howell, M.D. University of Michigan, Ann Arbor, 1863; a member of the Michigan State Medical Society, and for many years a member of the American Medical Association; from 1882 to 1886 a member of the legislature and for one term state senator; for fifteen years a member of the board of education, and one year president of the village of Tecumseh, Mich.; died at the home of his daughter in Macon township, September 14, from cerebral hemorrhage, aged 72.

James Galloway Buchanan, M.D. New York University, New York City, 1848; of Pittsburg, Pa.; local surgeon to the Pennsylvania System for 49 years; a member of the staff of the Allegheny General Hospital; surgeon of the Thirty-second and One Hundred and Twenty-fifth Ohio Volunteer Infantry throughout the Civil War; one of the oldest practitioners of western Pennsylvania; died at the home of his daughter in Pittsburg, September 14, aged 85.

John W. Coffin, M.D. Western Reserve University, Cleveland, 1889; a member of the American Medical Association; formerly of Beaver Falls, Pa.; major and surgeon of the Tenth Pennsylvania Infantry, U. S. V., during the Spanish-American War; and later in charge of the Bilibid Hospital, Manila; after his removal to Texas, captain and assistant surgeon in the Texas National Guard; died at his home in El Paso, September 16, aged 42.

George Lafayette Martin, M.D. College of Physicians and Surgeons, Baltimore, 1877; a member of the South Carolina Medical Association; for eight years supervisor of vaccination and quarantine for the Piedmont section of South Carolina under the State Board of Health; died at his home near Greenville, September 16, aged 55.

Richard S. Forsyth, M.D. Detroit (Mich.) College of Medicine, 1892; of Houston, Texas; a member of the American Medical Association; formerly local surgeon to the Northwestern System at Escanaba and physician of Delta county, Mich.; died at his summer home in La Porte, Texas, September 10, aged 42.

Joseph W. Wassall, M.D. College of Physicians and Surgeons, Chicago, 1884; of Chicago; a member of the American Medical Association; for several years dentist to the Czar of Russia; was washed from the deck of a yacht in Lake Michigan, off Racine, Wis., September 18, and drowned, aged 51.

Henry E. Thornton, M.D. Barnes Medical College, St. Louis, 1901; a member of the American Medical Association; died at his home in Maplewood, St. Louis, September 12, from the effects of carbolic acid, taken, it is believed, with suicidal intent, aged 30.

Philip G. Nichols, M.D. Missouri Medical College, St. Louis, 1872; for fifty years a practitioner of Pike county, Mo.; a clergyman of the Methodist Episcopal Church South; died at his home in Ashley, September 11, from cerebral hemorrhage, aged 69.

Benjamin L. Stovall, M.D Memphis (Tenn.) Hospital Medical College, 1884; of Lonoke, Ark.; a member of the Arkansas Medical Society; died in the Physicians and Surgeons' Hospital, Little Rock, Ark., September 14, from nephritis, aged 50.

William Benjamin Artz, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; for six years a member of the council of Osage City, Kan., and for four years mayor of the city, died at his home, September 12, from asthma, aged 59.

Julius B. Huber, M.D. Beaumont Hospital Medical College, St. Louis, 1896; of South St. Louis; a member of the Missouri State Medical Association; died in St. Anthony's Hospital, St. Louis, September 15, from tuberculosis, aged 49.

Alfred Meyers Fisher, M.D. Jefferson Medical College, Philadelphia, 1890; of McAlisterville, Pa.; died in Lebanon, Pa., May 22, from the effect of hydrocyanic acid, self-administered, it is believed with suicidal intent, aged 40.

Grenville Smith Stevens, M.D. College of Physicians and Surgeons, New York City, 1854; for more than half a century a practitioner of Providence, R. I.; died at his home in Edgewood, Providence, September 16, aged 80.

G. N. Harcy, M.D. University of Budapest, Hungary, 1848; surgeon in the Austro-Hungarian service, and exiled with Kossuth in 1852; died at his home in Bellevue, Ohio, September 14, from a congestive chill, aged 79.

Augustus Benjamin Southwick, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1867; physician to the Rome (N. Y.) City Hospital; died at his home in that city, September 11, from pneumonia, aged 69.

John Dambach, M.D. University of Buffalo (N. Y.), 1868; a member of the Medical Society of the State of New York; surgeon of volunteers during the Civil War; died at his home in Buffalo, September 15, aged 67.

Winfield Scott, M.D. Medical College of Ohio, Cincinnati, 1877; of Senecaville, Ohio; while making a professional call in Byesville, Ohio, died suddenly, September 14, from heart disease, aged 61.

John Sydenham Wilson, M.D. Kansas City (Mo.) Medical College, 1874; a member of the State Medical Association of Texas; died suddenly at his home in Houston, Texas, September 12, aged 59.

Ezra A. Palmer, M.D. University of Michigan, Ann Arbor, 1876; Northwestern University Medical School, Chicago, 1886; died at his home in Hartford, Mich., September 18, from nephritis, aged 62.

John Wheeler Pray, M.D. Harvard Medical School, Boston, 1879; a member of the New Hampshire Medical Society; died at his home in Northwood, June 19, from tuberculosis of the bowels, aged 57.

Charles Henry Springer, M.D. Wooster University, Cleveland, Ohio, 1882; of Cleveland; died in the Cleveland City Hospital, September 17, it is said, as the result of drug addiction, aged 48.

Fremont C. Warne (license, Mich., years of practice, 1900); one of the oldest practitioners of northern Michigan; died at his home in East Jordan, September 12.

William H. C. Moore, M.D. Rush Medical College, Chicago, 1867; died at his home in Essex, Iowa, September 4, from carcinoma of the stomach, aged 68.

Clarence Stephen Perry, M.D. Long Island College Hospital, Brooklyn, N. Y., 1885; died at his home in South Brooklyn, September 16, from pleurisy, aged 44.

Truman Squire Sumner, M.D. New York University, New York City, 1871; died at his home in Brooklyn, September 17, from nervous breakdown, aged 62.

Ernest E. Adelsberger, M.D. University of Maryland, Baltimore, 1902; died at his home in Baltimore, September 16, from tuberculosis, aged 30.

Daniel Young, M.D. formerly of Adolphustown, Ont., died at his home in Toronto, February 22, from edema of the lungs, aged 77.

Carl Schleifenheimer (license, Berks county, Pa.); died at his home in Reading, Pa., August 6, aged 81.

Sir Stephen Mackenzie, M.D. Aberdeen, 1875; M.R.C.S., England, 1869; F.R.C.P., London, 1879; of London, England; medical registrar and assistant physician of the London Hospital; formerly president of the Metropolitan Counties Branch and president of the section of medicine of the British Medical Association in 1897; formerly president of the Hunterian Society; lecturer on medicine and pathology in the London Hospital Medical Society; consulting [illegible] ondon hospitals; Lettsomiam lecturer [illegible] uptoms and treatment of anemia befor [illegible] of London in 1891; orator of the same society in 1902, when he delivered the annual oration on "The Powers of Natural Resistance, or the Personal Factor in Diseases of Microbic Origin;" an untiring research worker, whose labors on albuminuric retinitis, filariasis, sleeping sickness and anemia were especially notable; died at the home of his son in Dorking, Surrey, September 3, aged 64.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Medical Defense Adopted in Michigan

The Michigan State Medical Society at its recent meeting in Kalamazoo adopted the plan of medical defense proposed a year ago. The by-laws of the state society were amended so as to provide for: (1) an initial assessment of $1.50 from each member of the state society for the year 1910; (2) an annual per capita assessment thereafter of $1 per year; (3) a standing committee on medical defense consisting of an executive board of five and one member from each county society. The executive board is to be elected by the council for five years. The other members of the standing committees are to be elected by the county societies for one year. The chairman of the executive board, to be elected by the council of the state society for a term of one year, is to be the custodian of the defense fund. The executive board is authorized to retain by the year a competent firm of attorneys. Any member not in arrears is entitled to the benefits of the medical defense plan when sued or threatened with suit for civil malpractice. Dues must be paid before June 1. No member is entitled to defense in a suit the cause of which arose while the member was in arrears. Two years' liability is assumed for each member, provided suit was threatened or begun before the member joined the society or before the medical defense plan was established. Suits brought against the estate of a deceased member are also defended. All attorneys' fees and court costs are to be paid from the defense fund, but no damages assessed against any defendant will be paid. Each county society in the state is given the right to withdraw from the benefits of the medical defense plan on a majority vote of all of the members of the society.

The adoption of this feature by the Michigan State Medical Society is an extension of medical defense from the Wayne County Medical Society to the rest of the state, the plan having been first tested in Detroit. In many points the development of medical defense in Michigan is similar to that in Illinois, in which it was first taken up by the Chicago Medical Society, and later extended to the entire state. The proposed plan was submitted to the county societies and has been thoroughly and carefully discussed during the past year. Its adoption by a practically unanimous vote shows that the members of the state society were thoroughly convinced of the value of the plan. A number of objections similar to those raised in other states were made against the proposal. It is safe to say, however, that in the course of a year all of these objections will disappear in the light of practical experience and that the medical defense feature will become one of the most valued of membership privileges.

Medical Poor Relief in England

The supplement to the *British Medical Journal* for August 21 contains an address on "The Medical Aspect of the Report of the Royal Commission on Poor Law Reform" by Dr. H. Manley, President of the Birmingham branch of the British Medical Association. His discussion of medical relief of the poor is of particular interest in view of the recent consideration given the abuse of medical charities by some of our larger local organizations. Dr. Manley says: "The recent showing of the report of the Poor Law Commission has furnished me with an opportunity of discussing the grievous disabilities under which we are laboring as a profession. . . . [illegible]ver has there been a moment in our professional history [illegible]n there was greater need or greater opportunity for the general medical practitioners of this country to decide for themselves what is to be done for them and then to take united action to induce . . . the great departments of the state to recognize and to protect a body of its most highly trained citizens who are indispensable to its welfare and who receive a very scant return, either in cash or courtesy, for the services rendered to the public and to the government."

After discussing the lack of united action, which he considers the cause for this condition, Dr. Manley states that there are at present in England and Wales 3,713 physicians holding appointments as district medical officers, who in the past year attended 216,022 patients, in addition to those who were also in receipt of regular parish pay and to inmates of the poor law infirmaries. This relief he estimates to have cost about $2,500,000, which does not, however, represent the net income of the district medical officer, many of whom, according to the report of the Royal Commission, do not receive more than eight or twelve cents a visit. Dr. Manley also criticizes the details of administration and the character of relief afforded under the present poor law and concludes, "In plain English, a great part of this half million of money is spent in providing the poor with bottles of medicine—a dark medicine with a strong taste, preferably that of peppermint. . . . As the local medical humorist wrote, 'You just tell the medicine by the corks. If the cork is black you know it's the iron tonic; if it is stained brown with a crust on it, its the rhubarb and soda; and if it isn't any color at all it's the salts and the quassia. The pot. nit. you can tell by the taste, and the asafetida and bromid by the smell. And that's all, except the cough mixture, which smells of paregoric. It's only fools as wants prescription books.'"

Dr. Manley reviews at length the report of the Royal Commission as well as the minority report submitted by two members, and from the entire discussion draws the following conclusions: "It is abundantly evident that we are on the eve of great and sweeping changes in the administration of medical aid. The reform of the poor law . . . is inevitable. . . . Two schemes will be before the country: (1) The arrangement of all medical relief on a provident basis; (2) the establishment of a state medical service with power to the state to recover the cost from those who can afford to pay." Owing to the higher ratio existing in England between the number of physicians and the total population as compared with the United States, as well as the relatively larger number of persons coming under the operation of the poor laws in England, this question is one of great importance to the British medical profession. In both the question of contract practice and that of the administration of medical charities, we can learn much from the experiences of English physicians, and can perhaps profit by the attempts that have been and are being made in England to solve these questions equitably. The report of the Royal Commission, as well as the discussion thereon, should be read and carefully considered by those interested in similar problems in this country.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Second Month—First Weekly Meeting

DISEASES OF THE BRAIN

ANATOMY OF BRAIN

MEMBRANES OF BRAIN: (1) Dura mater—structure, attachments; (2) arachnoid—structure, subarachnoid space; (3) pia mater—structure.

PORTIONS OF BRAIN: Medulla, pons Varolii, cerebellum, midbrain, cerebrum.

VENTRICLES: Lateral, third, fourth, foramen of Majendie, aqueduct of Sylvius, communications, contents.

DISTRIBUTION OF GRAY MATTER: (1) In the bulb; (2) in the pons; (3) in the midbrain; (4) in the cerebrum; (5) in the cerebellum.

STRUCTURE OF BULB: Shape, size, surfaces, white matter, gray matter, pyramids, olives, restiform bodies, funiculi, corpora quadrigemina.

STRUCTURE OF PONS: Distribution of white and gray matter.

STRUCTURE OF MIDBRAIN: White and gray matter, aqueduct, fillet. Crus cerebri. Origin of cranial nerves.

CEREBELLUM: Vermis, hemispheres, peduncles, white and gray matter.

CEREBRUM: Hemispheres, corpus callosum, cortex, lobes, basal ganglia, corpus striatum, optic thalamus, internal capsule, corona radiata, projection fibers, association fibers, commissural fibers.

BLOOD-VESSELS: (a) To meninges; (b) to pia and brain substance. Circle of Willis and branches. Charcot's "artery of cerebral hemorrhage." Cerebral veins and sinuses.

PHYSIOLOGY OF THE BRAIN

SENSORI-MOTOR AREA: Fissure of Rolando, anterior and posterior central gyri, paracentral lobule, operculum, third frontal gyrus. Leg, arm and head regions. Hemiplegia, monospasm, Jacksonian epilepsy. Muscular sense, parietal lobes. Pressure, pain, temperature, sense.

SPEECH AREAS: Sylvian fissure, third frontal convolution, motor aphasia. First and second temporal convolutions, sensory aphasia. Visual speech area, lower parietal. Right- and left-handed persons.

SIGHT AREA: Occipital lobes, hemianopsia. Two visual centers.

Sound Area: First and second temporal convolutions.
Psychic Centers: Frontal lobes. "Silent Areas."
Functions of Cerebellum: Co-ordination, psychical functions, location of function.
Functions of Medulla: Respiratory and circulatory centers.
Cerebral Topography: Fissure of Rolando, fissure of Sylvius. Horseley's method, Kronlëin's method, Chiene's method.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-Second Annual Meeting, Held at Fort Wayne, Ind., Sept. 21-23, 1909

The President, **Dr. William Henry Humiston**, Cleveland, Ohio, in the Chair.

An address of welcome was made by Dr. H. A. Bruggemann, president of the Fort Wayne Medical Society, and was responded to by Dr. James Edgar Sadler, Poughkeepsie, N. Y.

Advantage of the Combined Intraperitoneal and Extraperitoneal Urethro-Lithotomy for Removal of Stones from Lower Ureter

Dr. Ernst Jonas, St. Louis: In this paper I call attention to the respective value of the various methods of examination in the diagnosis of ureteral stone and emphasize the importance of not relying on any one of these methods, but on a combination of all of them. Particularly important are repeated examinations of the urine, especially after attacks of kidney colic, and thorough physical examination with repeated vaginal and rectal examinations, good radiographs, and cystoscopic examination, with catheterization of the ureters.

The proper operation for the removal of stones from the lower ureter (brim of the pelvis down to the bladder) must not only offer the simplest technic but must permit an examination for possible etiologic factors, as adhesions around the appendix, tubes and ovaries, or retroflexion of the uterus. The above conditions may produce ureteritis, periureteritis, or increase the normal bend of the ureter to such a degree that it becomes kinked. As a result, small kidney stones may be arrested or increased in size in the ureter, or a stone may be primarily formed in the ureter and remain there *in situ*. The only operation which enables us to remove these causes for ureteral stone and thus prevent recurrence of the stone is the combined intraperitoneal and extraperitoneal ureterolithotomy. The intraperitoneal steps serve for the repair or removal of such pathologic conditions, and in addition facilitate the finding of the ureteral stone. The extraperitoneal steps serve for the removal of stone. I advocate, therefore, that the combined intraperitoneal and extraperitoneal ureterolithotomy become the typical operation for the removal of stones from the lower ureter.

DISCUSSION

Dr. John Young Brown, St. Louis: In my own work, and in watching the work of others, I have frequently been impressed with the fact that the appendix may be removed when macroscopically there seems to be no indication that it was at fault. The anatomic relationships of the appendix and ureter are interesting. During the last year I have been studying this by cross-section work and by injecting the appendix with bismuth, doing skiagraphic work in all cases sent to my clinic with a diagnosis of appendicitis, in which I have found stones in the ureter, but in which the appendix was not diseased. I do not know of any condition that is more difficult to differentiate than certain forms of chronic appendicitis and stones in the ureter. In the last year I have had nine cases, three of them being in physicians in whom the differential diagnosis was exceedingly difficult. In one case I found a shadow of a supposed stone in the ureter, which proved to be a concretion in the appendix. I removed the appendix, which was retrocecal. In another case a physician's brother was sent to me with a diagnosis of appendicitis. I found blood in the urine. Roentgen examination seemed to indicate stone in the ureter. I did the combined operation, and removed not only a stone from the ureter but the appendix, which was adherent to the right ureter, and I am inclined to believe that the condition around the appendix had a good deal to do with the development of the stone in the ureter.

Dr. A. H. Ferguson, Chicago: A man presented himself at the Chicago Hospital on Sept. 15, 1909, with the following history: Four years ago he had a very severe attack of kidney colic, in the left kidney. He was laid up two weeks, and since then has had several minor attacks, referable to the region of the ureter. The patient is a healthy man of 58. The radiographs showed a stone in the lower end of the left ureter, between one and two inches from the bladder. The sound and cystoscope revealed nothing of the nature of calculus in the bladder. The left ureteral orifice protruded somewhat and was a trifle redder than normal. The patient was given, besides the usual preparation for laparotomy, hexamethylenamin and methylen blue. The anesthetic was ether, given by the drop-method. A skin incision was made directly over the external ring, extending upward along the course of the inguinal canal for five inches. The aponeurosis of the external oblique muscle was opened freely, exposing the entire inguinal region, and internal oblique muscle. The internal abdominal ring was enlarged without opening the peritoneal cavity. The transversalis fascia was severed along the entire length of the incision, exposing the deep epigastric vessels which were ligated and cut. The vas deferens was taken as the guide to the ureter. It was followed by blunt dissection to the base of the bladder. The sigmoid and small bowel were pressed toward the median line by gauze sponges. To obtain sufficient room to admit the hand, the origin of the internal oblique and transversalis muscles was severed from Poupart's ligament for a distance of two inches. This afforded room to reach and explore the ureter from the pelvic brim to the base of the bladder. The stone was felt in the ureter. An effort was then made to milk it into the bladder or toward the kidney. Both these measures proved impossible. An incision was made into the ureter, parallel to its long axis, about one inch below the brim of the pelvis. A stout catgut ligature had been passed around the duct as a guy-rope. The ureter was empty. There was no staining of the tissues with methylene blue. It was thus evident that anuria existed in the left kidney. An olive, flexible, bougie was passed into the ureter and the stone located. The grating of the probe against the stone could be distinctly heard. Another attempt was made to shove the stone into the bladder, but it was unsuccessful. Then a long, curved, alligator-jawed forceps was passed into the opening in the ureter. The stone was seized in its blades and carefully extracted. The entire course of the ureter from kidney to bladder was explored and found perfectly clear. No attempt was made to suture the ureter. The loose tissues on either side of the wound were drawn together, and the same suture caught about a gauze drain, covered with rubber tissue. This drain was brought out, at the upper angle of the wound. The cord was left behind the transversalis fascia. This structure, with the transversalis and internal oblique muscles were sutured to Poupart's ligament. The lower angle of the wound was drained with a cigarette drain which passed down to the side of the bladder. The external oblique was closed with continuous catgut suture, and the skin with silkworm gut sutures. A catheter was passed into the bladder to keep it empty. The procedure varies with the side of the body. If the colicky attacks are on the right side, the appendix must be thought of, and there is an indication for opening the abdomen. If the attacks are on the left side, and the patient is a man, there is no indication for opening the abdomen because such a stone can be removed more safely without the complication of an additional cut in the peritoneum. In women these stones can be reached through the bladder, when they are low down, depending on the size, etc.

Dr. H. W. Longyear, Detroit: I have seen many operations on the appendix that were not justified and were prompted by the pain in the ureter under a mistaken diagnosis. In these cases we see more or less of what we may call storms of uric acid coming from intestinal toxemia. Large quantities of uric acid are thrown out from the kidney, passed down the ureter, causing inflammation of the ureter and pain, and when the pain is on the right side the condition is apt to be mistaken for appendicitis, and the temperature arising from the toxemia simulates appendicitis still more.

Dr. Miles F. Porter, Fort Wayne, Ind.: I recall a recent case in which there was typical ureteral colic and anuria. The patient had had nephritis for years. In this case, as the subsequent post-mortem revealed, there was no calculus formation whatever. Moreover, the case illustrated the value of the skiagraph. The skiagram in this case showed no ureteral calculus.

Dr. C. C. Frederick, Buffalo: There is no question but what there are many cases of pain in the right ureter for which the appendix in the past has been blamed and removed. I have seen a number of cases of this kind in my own practice as well as in that of others, and I have been forced during the last three or four years to a realization of the fact that pain on the right side on pressure deep down over McBurney's point does not always mean that a patient has chronic appendicitis, and I believe that in many instances the trouble is in the ureter.

Dr. M. I. Rosenthal, Fort Wayne, Ind.: Four or five years ago I reported a case of ureteral stone, complicating appendicitis. This was the only case I had then seen of ureteral calculus complicating appendicitis. Since then I have been careful to investigate the right ureter in operations for appendicitis, but I have not seen another such case. This would indicate that this complication is not frequent, although it does occur.

Dr. Hugo O. Pantzer, Indianapolis: In operating on a case of gangrenous cholecystitis, with a discharge of the contents of the gall-bladder into the peritoneal cavity, I was led to examine lower down and found that at the bifurcation of the abdominal aorta a number of stones which were hard and fixed to the feel. I removed one of these stones and found it to be a calcareous degeneration of tuberculous glands. The history of the case would seem to show that this woman, 50 years of age, had in early life a tuberculosis of this part.

Dr. John W. Keefe, Providence, R. I.: In one case I introduced a wax-tipped catheter and found markings on the wax. The catheter was introduced in the pelvis of the kidney, and on the day the patient was to be operated on I again passed the wax-tipped catheter to the kidney, made my incision in the loin, and found the catheter in contact with a stone in the kidney, showing that the first markings on the wax were correct.

Dr. K. I. Sanes, Pittsburg, cited a case illustrating the difficulty of making a differential diagnosis between ureteral trouble and appendicitis, saying that this difficulty is not only encountered in chronic but in acute cases of appendicitis.

Forty-Fourth Annual Meeting, held at Kalamazoo, Sept. 15-16, 1909

(Continued from page 1048)

Syphilis of the Liver—Unusual Types

Dr. A. R. Edwards, Chicago: Syphilis of the liver is not fully appreciated either in practice or in the literature. Syphilis of the liver typically includes gummata and syphilitic cirrhosis. Aside from the close resemblance to cancer frequently presented by large and multiple gummata, cancer is frequently simulated by hepatic syphilis when gummata in the liver are attended by pain, ascites, icterus and emaciation. Alimentary symptoms are common in hepatic syphilis. A luetic cachexia may make differentiation impossible except by the therapeutic test, etc. In a second group of cases, gummata may exactly mimic abscess of the liver; deception is most likely when gummata cause fever, chills, hepatic tenderness, pain and enlargement; leucocytosis, emaciation and even fluctuation may be observed also. In a third series, local hepatic symptoms are lacking and the rigors, fever, sweats, etc., may simulate malaria, typhoid, tuberculosis, or septicopyemia; the course may cover weeks or months. In a fourth group, gall-stones, cholecystitis or calculous obstruction of the common duct are suggested until the specific remedies or operation disclose the error. In the fifth group the symptoms are almost identical with those of alcoholic cirrhosis; even in far-advanced cases recovery may ensue under mercury and iodids. The sixth type is syphilitic pylephlebitis, of which an exceptional instance was reported; the course covered over four months and was first diagnosticated septic pylephlebitis. There was sudden pain over the portal vein with a precipitate and extreme ascites, great variations in temperature which frequently rose and fell six or eight degrees in a day, severe rigors, and profound anemia and emaciation. Rather late, syphilis was considered and recovery was immediate.

DISCUSSION

Dr. W. F. Breakey, Ann Arbor, Mich.: In acquired syphilis particularly, and that in early life the activity of this large gland must account in a large degree for the liver being the seat by preference of all the attacks of syphilis on the abdominal viscera. In all cases a thorough investigation should be made to determine the diagnosis. Many patients consult a physician with an obscure history or none at all; and even when a patient does not intend to deceive there may be abundant reason for suspecting syphilis. The period of latency is usually uncertain, and it may cover a considerable number of years, and while the physician may prescribe treatment as an aid to diagnosis, yet he is entirely justifiable in so doing when other measures have been followed and no clew results. If with the modern tests for syphilis the *Spirochæta pallida* is found, the way is clear, and there is no hesitation as to what to do. If the spirochetes are not found, and they often are not, and a longer period elapses during which the disease is suspected, in the absence of clear and definite physical signs by which we may determine carcinoma or nodular conditions of the liver, it is right, in my opinion, to try antisyphilitic treatment. Our function as physicians is to treat this disease and to lessen it, if it is not possible for us to stamp it out. I do not see why it is not just as feasible to try to stamp out syphilis as tuberculosis. There is need for higher requirements by teaching bodies and examining boards on the subject of syphilis. We should encourage the study of this disease, and one essential thing is to disabuse the public mind of the disgrace of it, because so many patients who have the disease have acquired it innocently.

Dr. Andrew P. Biddle, Detroit: I wish to refer specifically to gummatous lesions, and would emphasize the point that time has no limits in the formation of gumma. While it is usually taught that gumma is a late-appearing lesion, yet we know that a patient may have gumma in certain forms of destructive syphilis as early as the first few months. Another point is the relationship of syphilis to other obscure conditions. When we consider that the influence of syphilis is particularly on the blood-vessels and on the nervous system, we can easily see why there is such a variety of manifestations. We know how difficult it is, even when we see cancer on the face, to differentiate it from some of the lesions of syphilis, and it is no wonder that it is difficult sometimes to differentiate these lesions when they involve the internal organs. It is difficult with all the manifestations present to differentiate between cancer of the liver or simple gummatous formation of the liver.

Dr. J. Collins Johnston, Grand Rapids: As an illustration of the good results of what we may call the diagnostic use of syphilitic treatment in doubtful cases of the kind referred to by Dr. Edwards, I want to report briefly an interesting case in my own experience. A year-and-a-half ago I was called to see a man in a little town near Grand Rapids who had been ill for several months, the prominent symptoms being those of alcoholic cirrhosis of the liver. He had been in the hospital two or three weeks and had been seen by several physicians, all of whom diagnosed either cancer of the liver or alcoholic cirrhosis. He went to Ann Arbor and was sent home to die of alcoholic cirrhosis of the liver. I do not know what prompted me to think the case might be syphilitic. It was decided by the attending physician and myself that the man had no hope if the diagnosis already made was correct. He had been in bed several weeks. He had been tapped a number of times, large quantities of liquid being removed from the abdomen. We put him on hypodermics of mercury and iodids internally. Under this treatment he improved rapidly, and two or three months later appeared in my office. I have seen him several times during the last year and apparently he is absolutely well, but his liver still remains large. I would like to ask Dr. Edwards if in a case of hypertrophic cirrhosis or syphilitic cirrhosis the liver ever returns to its normal size.

Dr. Frank Smithies, Ann Arbor: Three cases have come under my notice recently, all of which gave the hemolytic test by the original Wassermann procedure. One case particularly had been diagnosed as pernicious anemia, on account of anemia and symptoms of cachexia; it had also been diagnosed as carcinoma. The patient vomited constantly, lost 60 pounds, and altogether was in a bad way. The Wassermann test revealed the absence of hemolysis. The patient, after having vigorous lavage, promptly stopped vomiting, and was put on combined treatment. I saw him recently and he has gained within two pounds of his gross weight, and feels well in every way. A patient seen last year had an epigastric tumor, but there were no marked gastric symptoms. The patient insisted on being operated on; a portion of the tumor was removed and was found to be a gumma of the liver. A third case showed a roundish tumor in the epigastrium, which appeared to be beyond the stomach. The stomach could be inflated and did not move the tumor, which did not have any relation to the large bowel. It had no relation apparently to the liver, yet on opening the abdomen it was found to be a large gumma that had a deep connection with the liver; it cleared up to a certain degree under the combined treatment. All these patients gave the Wassermann reaction by the original procedure. The first patient has not given such a prompt reaction since the beginning of the combined treatment.

Dr. Morton, Battle Creek: I would emphasize the fact that there is such a thing as luetic fever. In the last three or four years I have had three cases that puzzled me a great deal. These patients had been treated for tuberculosis. One of them had been kept on the usual dietetic and fresh air treatment for nearly three months, and kept a regular temperature chart. He came under my care, and I could find nothing the matter with his lungs. I could not find any evidence of trouble in the respiratory tract. The man gave a history of having had syphilis seventeen years previously. I observed him for a few days, during which time the temperature ranged from 102 to 104 F. every afternoon, and in the morning it ranged from 99 to 100 F. I had read Janeway's article on luetic fever, and had also seen cases reported, and I tried the iodid treatment. In two days his temperature was normal, and two days later he had no further trouble. The other two patients behaved in the same way. It should be impressed on the minds of practitioners, therefore, that there is such a thing as luetic fever. In the cases mentioned, there was no enlargement of the liver, and I could find no abnormal condition of any of the organs of the body.

Dr. W. M. Donald, Detroit: Is it not a fact, borne out by autopsies, that hepatic syphilis in prenatal or postnatal life is of the interstitial type? Is it not a fact that hepatic syphilis in later life is almost entirely gummatous?

Dr. Arthur R. Edwards, Chicago: It is true that interstitial hepatitis is more frequent in the hereditary than in the acquired type of syphilis: and the converse is true, although either form may be observed in either type of syphilis. As a rule, the liver remains larger afterward, although in some instances there is apparent recovery. In other instances the liver becomes smaller than normal. With regard to cases resembling pulmonary tuberculosis, the type described by Janeway, and suggesting tuberculosis in the absence of any visceral findings, one cannot say in such instances that temperature of that variety is always due to syphilis of the liver. It may be due to syphilis of the bones, or to syphilis of any of the viscera. I think that the hypodermic method of treating these patients gives more rapid results than any other method of administering the mercury, although it is sometimes painful and some patients will not tolerate it.

Aneurism of the Descending Thoracic Aorta

Dr. Johann Flinterman, Detroit: This condition is rare. In aneurism of the descending aorta, which often escapes detection, the earliest symptom is pain, and the patient complains of it before there is a single other physical sign or indication of the presence of a tumor. One patient, a man of 43, had an aneurism of the descending aorta. He suffered for a long time with severe pain only, and after it, about a year and a half later, from cough, dyspnea, then stridor, expectoration of blood, and paresis of the left recurrent nerve. Syphilis and lead poisoning were suspected. The diagnosis of aneurism is easy in many cases, but in others extremely difficult, often impossible. Auscultation, the condition of the heart and arteries, symptoms due to intrathoracic pressure, and most of all, the Roentgen rays, are the means of helping in the diagnosis.

DISCUSSION

Dr. A. S. Warthin, Ann Arbor: Syphilis plays the chief, if not the entire part in the etiology of aortic aneurism. The Wassermann reaction, and more recent studies of the lesions confirm the old pathologic view that these aneurisms are syphilitic in origin.

Dr. Hugo A. Freund, Detroit: It was my good fortune to witness the post-mortem examination on the case reported by Dr. Flinterman. It was an unusual aneurism, in that its dilatations were saccular from the main fusiform dilatation. There were three separate ones which went out in different directions, one going upward and backward, adherent to the long, and posterior surface of the ribs, as well as posterior part of the chest. The other dilatation went distinctly outward and to the left. The one from which rupture took place was over the surface of the left bronchus. The left lung was filled with blood, and was absolutely airless. There was considerable fluid in the left pleural cavity. The effusion was old and had been brought about by some process of irritation. There was nothing else in the lung. Even with the *x*-ray it was impossible to make a diagnosis of this aneurism, yet the post-mortem revealed an unusual specimen.

Dr. J. Collins Johnston, Grand Rapids: I wish to report a case illustrating the value of the *x*-ray in the diagnosis of aneurism. Several years ago a man came to me who had great pain in the side of the neck, which had continued for two years. For three months he had a slight swelling at the junction of the strenum, and left clavicle and soreness on pressure. This swelling was of the hardness of stone, and was circumscribed. Percussion did not show any dulness to the right of the sternum, and for about an inch to the left, extending down to the second interspace, there is a point of interest in connection with what the *x*-ray picture showed. There were no physical signs of aneurism other than that. At my first examination I thought it might be syphilitic, tuberculous, or some osteomyelitic disease, due to some other cause. There was no difference in the radials, no signs of pressure on the bronchus or esophagus. The heart was normal and in its location. The sounds at the apex and base were normal. There was no accentuation of the second sound. I sent the patient to an *x*-ray man and he got a beautiful picture of aneurism of the ascending aorta. The picture showed that the aneurism extended a good deal farther to the left of the sternum than to the right. The tumor was a little larger than a dollar, and only a small part of the aneurism presented to the front. The man is now taking large doses of iodid of potassium.

Dr. A. R. Edwards, Chicago: I believe that practically all aneurisms are syphilitic, and this is borne out positively both pathologically and clinically.

(*To be continued*)

can be removed more safely without the complication of an additional cut in the peritoneum. In women these stones can be reached through the bladder, when they are low down, depending on the size, etc.

Dr. H. W. Longyear, Detroit: I have seen many operations on the appendix that were not justified and were prompted by the pain in the ureter under a mistaken diagnosis. In these cases we see more or less of what we may call storms of uric acid coming from intestinal toxemia. Dr. J. Collins Johnston, Grand Ra
tion of the good results of what we ma
use of syphilitic treatment in doubtf
kind referred to by Dr. Edwards. I w
briefly an interesting case in my own ex
year-and-a-half ago I was called to see a man

town near Grand Rapids who had been ill for several months, the prominent symptoms being those of alcoholic cirrhosis of the liver. He had been in the hospital two or three weeks and had been seen by several physicians, all of whom diagnosed either cancer of the liver or alcoholic cirrhosis. He went to Ann Arbor and was sent home to die of alcoholic cirrhosis of the liver. I do not know what prompted me to think the case might be syphilitic. It was decided by the attending physician and myself that the man had no hope if the diagnosis already made was correct. He had been in bed several weeks. He had been tapped a number of times, large quantities of liquid being removed from the abdomen. We put him on hypodermics of mercury and iodids internally. Under this treatment he improved rapidly, and two or three months later appeared in my office. I have seen him several times during the last year and apparently he is absolutely well, but his liver still remains large. I would like to ask Dr. Edwards if in a case of hypertrophic cirrhosis or syphilitic cirrhosis the liver ever returns to its normal size.

Dr. Frank Smithies, Ann Arbor: Three cases have come under my notice recently, all of which gave the hemolytic test by the original Wassermann procedure. One case particularly had been diagnosed as pernicious anemia, on account of anemia and symptoms of cachexia; it had also been diagnosed as carcinoma. The patient vomited constantly, lost 60 pounds, and altogether was in a bad way. The Wassermann test revealed the absence of hemolysis. The patient, after having vigorous lavage, promptly stopped vomiting, and was put on combined treatment. I saw him recently and he has gained within two pounds of his gross weight, and feels well in every way. A patient seen last year had an epigastric tumor, but there were no marked gastric symptoms. The patient insisted on being operated on; a portion of the tumor was removed and was found to be a gumma of the liver. A third case showed a roundish tumor in the epigastrium, which appeared to be beyond the stomach. The stomach could be inflated and did not move the tumor, which did not have any relation to the large bowel. It had no relation apparently to the liver, yet on opening the abdomen it was found to be a large gumma that had a deep connection with the liver; it cleared up to a certain degree under the combined treatment. All these patients gave the Wassermann reaction by the original procedure. The first patient has not given such a prompt reaction since the beginning of the combined treatment.

Dr. Morton, Battle Creek: I would emphasize the fact that there is such a thing as luetic fever. In the last three or four years I have had three cases that puzzled me a great deal. These patients had been treated for tuberculosis. One of them had been kept on the usual dietetic and fresh air treatment for nearly three months, and kept a regular temperature chart. He came under my care, and I could find nothing the matter with his lungs. I could not find any evidence of trouble in the respiratory tract. The man gave a history of having had syphilis seventeen years previously. I observed him for a few days, during which time the temperature ranged from 102 to 104 F. every afternoon, and in the morning it ranged from 99 to 100 F. I had read Janeway's article on luetic fever, and had also seen cases reported, and I tried the iodid treatment. In two days his temperature was normal, and two days later he had no further trouble. The other two patients behaved in the same way. It should be impressed on the minds of practitioners, therefore, that there is such a thing as luetic fever. In the cases mentioned, there was no enlargement of the liver, and I could find no abnormal condition of any of the organs of the body.

Dr. W. M. Donald, Detroit: Is it not a fact, borne out by autopsies, that hepatic syphilis in prenatal or postnatal life is of the interstitial type? Is it not a fact that hepatic syphilis in later life is almost entirely gummatous?

Dr. Arthur R. Edwards, Chicago: It is true that interstitial hepatitis is more frequent in the hereditary than in the acquired type of syphilis: and the converse is true, although either form may be observed in either type of syphilis. As a rule, the liver remains larger afterward, although in some instances there is apparent recovery. In other instances the liver becomes smaller than normal. With regard to cases resembling pulmonary tuberculosis, the type described by Janeway, and suggesting tuberculosis in the absence of any visceral findings, one cannot say in such instances that temperature of that variety is always due to syphilis of the liver. It may be due to syphilis of the bones, or to syphilis of any of the viscera. I think that the hypodermic method of treating these patients gives more rapid results than any other method of administering the mercury, although it is sometimes painful and some patients will not tolerate it.

Aneurism of the Descending Thoracic Aorta

Dr. Johann Flinterman, Detroit: This condition is rare. In aneurism of the descending aorta, which often escapes detection, the earliest symptom is pain, and the patient complains of it before there is a single other physical sign or indication of the presence of a tumor. One patient, a man of 43, had an aneurism of the descending aorta. He suffered for a long time with severe pain only, and after it, about a year and a half later, from cough, dyspnea, then stridor, expectoration of blood, and paresis of the left recurrent nerve. Syphilis and lead poisoning were suspected. The diagnosis of aneurism is easy in many cases, but in others extremely difficult, often impossible. Auscultation, the condition of the heart and arteries, symptoms due to intrathoracic pressure, and most of all, the Roentgen rays, are the means of helping in the diagnosis.

DISCUSSION

Dr. A. S. Warthin, Ann Arbor: Syphilis plays the chief, if not the entire part in the etiology of aortic aneurism. The Wassermann reaction, and more recent studies of the lesions confirm the old pathologic view that these aneurisms are syphilitic in origin.

Dr. Hugo A. Freund, Detroit: It was my good fortune to witness the post-mortem examination on the case reported by Dr. Flinterman. It was an unusual aneurism, in that its dilatations were saccular from the main fusiform dilatation. There were three separate ones which went out in different directions, one going upward and backward, adherent to the long, and posterior surface of the ribs, as well as posterior part of the chest. The other dilatation went distinctly outward and to the left. The one from which rupture took place was over the surface of the left bronchus. The left lung was filled with blood, and was absolutely airless. There was considerable fluid in the left pleural cavity. The effusion was old and had been brought about by some process of irritation. There was nothing else in the lung. Even with the x-ray it was impossible to make a diagnosis of this aneurism, yet the post-mortem revealed an unusual specimen.

Dr. J. Collins Johnston, Grand Rapids: I wish to report a case illustrating the value of the x-ray in the diagnosis of aneurism. Several years ago a man came to me who had great pain in the side of the neck, which had continued for two years. For three months he had a slight swelling at the junction of the strenum, and left clavicle and soreness on pressure. This swelling was of the hardness of stone, and was circumscribed. Percussion did not show any dulness to the right of the sternum, and for about an inch to the left, extending down to the second interspace, there is a point of interest in connection with what the x-ray picture showed. There were no physical signs of aneurism other than that. At my first examination I thought it might be syphilitic, tuberculous, or some osteomyelitic disease, due to some other cause. There was no difference in the radials, no signs of pressure on the bronchus or esophagus. The heart was normal and in its location. The sounds at the apex and base were normal. There was no accentuation of the second sound. I sent the patient to an x-ray man and he got a beautiful picture of aneurism of the ascending aorta. The picture showed that the aneurism extended a good deal farther to the left of the sternum than to the right. The tumor was a little larger than a dollar, and only a small part of the aneurism presented to the front. The man is now taking large doses of iodid of potassium.

Dr. A. R. Edwards, Chicago: I believe that practically all aneurisms are syphilitic, and this is borne out positively both pathologically and clinically.

INTERNATIONAL CONFERENCE ON LEPROSY

(Held in Bergen, Norway, Aug. 16-19, 1909)

(Continued from page 1046)

Transmission of Leprosy

Dr. Dehio, of Dorpat, Russia, maintained very emphatically the contagiousness of leprosy. Ehlers, of Copenhagen, referred to his experiments with parasitory human in sects which have been considered capable of spreading this disease, especially pulex and cimex lectularius, but he was not able to come to any determined conclusion. Dr. Sand of Trondhjem, Norway, in his thirty-five years' experience in the leprosarium of that city, having treated 1,558 lepers, has come to the conclusion that leprosy is not transmitted by immediate contact.

Dr. V. Dühring, Dresden, discussed hereditary transmission of leprosy. He has found that the disease affects the descendants so far as to deteriorate the race. The offspring of lepers are more subject to mortality, and, moreover, they show a disposition to acquire with infectious diseases, as tuberculosis. The transmission of leprosy from parents to children biologically and clinically is in no way probable. The direct transmission of leprosy to the fetus *in utero*, although theoretically possible, has never been proved.

Psychoses of Lepers

Dr. Moreina, of Rio de Janeiro, called attention to the psychoses of the lepers. He believes that in lepers there is no peculiar kind of insanity. Only the polyneuritic leprosy can be accompanied by the whole syndrome of Korsakow. At the onset of the disease not often can be found any kind of mental alienations. In many cases complications of leprosy, as tuberculosis, streptococcus infections, or arteriosclerosis may be cause of mental trouble in the lepers. The ordinary mental condition of the patients affected with leprosy is different and is greatly influenced by the duration of the disease, by the age, by education and the clinical forms of the disease.

Mental Disturbances in Leprosy

Professor de Beurmann, Paris, discussed the mental troubles in leprosy and the psychism of the lepers. He called attention to the mental condition of the lepers in the extreme East, which is far different from that of the Europeans. The Hindoos, the Malays and the Mongolians, although blind, mutilated and in the most terrible general condition, never [illegible]ow signs of mental trouble. In Asiatic asylums have been [illegible]und lepers jovial and satisfied with their condition. In consequence, the sadness and the despondency of the European lepers is more due to their education and to the consciousness of having a disease of hopeless prognosis.

Treatment

The meeting on Wednesday, August 18, was devoted entirely to therapy. Dr. von Deycke, of Hamburg, discussed nastin injections. Nastin is obtained as a neutral grease from the culture of a kind of streptothrix and it seems to be identical with the neutral fat obtained from the tubercle bacillus. This so-called streptothrix has been called *streptothrix leproides*, but has no other relation to the true leprosy bacillus than to contain a kind of nastin fat. The pure nastin has the ability to produce in some of the lepers more or less reaction of general or of local nature. The reaction is subject to the greatest oscillation. While some patients are absolutely refractory to its action, others show symptoms of so severe a nature as to jeopardize life. For these reasons nastin alone cannot be used in the treatment of leprosy. When nastin is mixed with such substances which *in vitro* remove the grease from acid-fast bacilli, like tubercle bacilli, then we obtain a preparation, which can be used as therapeutic means. One preparation is nastin-B., which is nastin combined with benzoyl chlorid in an oily solution. According to the degree of concentration, nastin-B. does not usually produce a very intense reaction, and can be obtained in a form which will not cause any reaction at all. Although nastin-B. is therapeutically much more sure and constant in its action than pure nastin, yet in individual cases it shows different action. Nastin-B. acts directly on the specific cause of leprosy in the sense of bacteriolysis, as it prepares the bacilli, by removing their fat, to be susceptible to bacteriolysis. In a large percentage of lepers treated with nastin-B. improvement has followed in the general feeling. Moreover, it seems that it has prevented the farther progress of the leprous process. The nastin treatment has to be continued for one year, in form of an intermittent therapy just as it is used in syphilis.

Treatment of Ophthalmic Diseases in Lepers

Dr. Lyder Barthen, Trondhjem, Norway, spoke first on treatment of non-leprous diseases in leprous eyes, then on the genuine leprous diseases of the eyes, finally the last stages of the leprous eye diseases and their treatment.

Nastin Treatment in Russia

Dr. E. Kiwull, Wenden, Livonia, Russia, spoke on his experience with nastin treatment in the leprosarium of Wenden. He had used only nastin-B. The injections although painful were well-borne. After the injection only an increase in the temperature occurred. In the symptoms during the treatment some better and some worse could be found. Frequently ulceration occurred of old infiltrations in tubercules and in scars. In several cases swelling and pains occurred in the ulnar nerve and its ramifications. It was often remarked that hard tubercles imbedded in the depth of the skin disappeared under its action leaving only a slight pigmentation. Ulcerations of the hard palate become much more flat and showed a tendency to heal up. Examination of the blood showed that nastin increased the number of leucocytes.

Nastin Treatment in Australia

Dr. J. Ashburton Thompson, Sidney, is greatly opposed to the use of nastin. He employed the injections in 5 selected cases: 4 of tuberculous leprosy and 1 of pure leprosy of the nerves. He continued the treatment for from 6 to 9 months. In 3 of the patients the disease remained as it was. In the nervous case, the pains increased. A child became much worse. He claims that nastin is an inert substance with some irritant and also caustic effects on the seat of injection. In none of the patients did the injection produce any local reaction, or any fever.

Treatment of Leprosy

Dr. H. P. Lie, Bergen, Norway, maintained that the nastin treatment is in no way a specific treatment, and the reactive symptoms produced by the injections of nastin in the lepers is nothing but a reaction which f[illegible]s the injection of any fatty substance from acid-fast [illegible] The same action is found in patients affected with [illegible]sis. It is necessary to be very careful with nasti[illegible]ents with a tendency to tuberculosis show[illegible]ction. He considers the nastin treatment. [illegible] forward toward the betterm[illegible] of this [illegible] of good results obtained [illegible] he met[illegible] from other treatment[illegible] the e[illegible]ho for 12 years had su[illegible] sym[illegible] th[illegible] last eight year[illegible] patient can be [illegible] actic[illegible] ment was entire[illegible]

[illegible] of [illegible]

Dr. J. M. H. [illegible] Lond[illegible] of the last 12 [illegible] more bacillus of Han[illegible] pecific special stai[illegible] is [illegible] young, old and [illegible] th[illegible] methods it has [illegible] t t[illegible] found in the t[illegible] Th[illegible] arrangement [illegible] his [illegible] that the lepra [illegible] the [illegible] No medium has [illegible] be cultivated, [illegible] oof as saprophytes on decayed organic matter, decayed fish, etc. No lower animals have been found susceptible to leprosy. The presence of bacilli in gnats and bed-bugs suspected of disseminating the disease is still doubtful. The way of entrance of the bacilli into the organism is still obscure; it may be by the nasal mucosa and the upper respiratory tract, or the infection may be from the alimentary tract, or through the genitals; perhaps through the skin.

So far there is no clear idea concerning the relation of maculo-anesthetic and nodular leprosy. May it be due to the quantity of bacilli which cause nodular leprosy, due probably to racial peculiarity, climatic condition and absence of hereditary or acquired immunity. It may also be due to a qualitative difference in the virulence of the bacilli. The pathologic lesions produced in the tissues by the direct or indirect action of the bacilli are the production of the infective granuloma. In the beginning, the bacilli are outside of the cells, but later many gain entrance and multiply therein. Obscurity still surrounds the cells which may be connective-tissue cells or plasma cells containing bacilli, or may be clusters of bacilli around a nucleus or a lymphocyte, or may be masses of bacilli accumulated in lympatic spaces. In skin lesions, the bacilli are found in the corium, but may be present in the epidermis and in the surface of the skin. Not yet clear is the manner in which the bacilli reach the surface, it is possible that they pass through the interepithelial lymphatics, or by the sweat or through the epithelial cells, and from without being deposited by the nasal discharge or by the sputum. Not much has been added to the knowledge of visceral leprosy. In the spleen true leprous infiltration occurs, and also in the lungs, where caseation and necrosis are often found. Bacilli have been found in the glomeruli of the kidneys, in the epithelium of the uriniferous canals, but not in the urine. The genitals, ovaries and testicles have been found extensively affected with leprosy, but yet the bacilli have never been found in the Graffian follicles, in the seminiferous tubules, or in the semen. Bacilli have been found in the blood, but as it has been taken from the lepromata it may be that bacilli were taken from the lymph. The blood shows all characteristics of anemia with a slight eosinophilia.

Leprosy of the eye is a late manifestation of nodular leprosy, only rarely primary. It is possible that the infection takes place in consequence of the general infection as the chorioid is the chief site of the disease and the cornea is involved after the deeper parts. It is also possible that the infection takes place from without, the conjunction being infected first, then the cornea, corneosclerotic limbus, ciliary body and finally the uveal tract. Diversity of opinion is found in reference to the pathogenesis of maculo-anesthetic leprosy. It has not yet been decided whether the maculo-anesthetic lesions are identical with those of the nodules, and have to be considered as an early stage of the skin lesion, or whether they are to be considered as a form of inflammatory process of the type of erythema persistans. Peripheral nerves may be affected in all forms of leprosy, but more markedly in the maculo-anesthetic type. The presence of the bacilli and of their toxins leads to neuritis and interstitial proliferative alterations, which by pressure on the vital nerve tissue cause degeneration of the axis cylinder. It seems that the neuritis so produced causes eventual destruction of the bacilli and consequently leprosy of the nerves is self-curative. It is doubtful if the spinal cord and the ganglia are affected by the bacilli, and it is also possible that the changes which take place in the posterior columns of the cord are not due to the bacillus *in situ*. These changes are not characteristic, and resemble the changes following the ascending degeneration of a peripheral nerve from injury or as the results of general cachexia. The possibility of the association of leprosy with other diseases as tuberculosis, syphilis, etc., must not be forgotten, and the ravages of these associated diseases must not be attributed to leprosy.

Blood Reactions in Lepers

Dr. Babes, Bucharest, spoke on the reactions of the blood in the lepers: it seems that there is nothing specific to give much light on the subject.

Dr. George Meyer, Berlin, maintained that the lepra serum gives the same reaction as the serum in syphilis, only in cases of the tuberculous type.

Bone and Joint Changes in Leprosy

Professor Harbitz, Christiania, Norway, spoke on the leprous alteration of the bones and joints from trophoneurotic causes. The hands and the feet, especially at the tarsal and carpal joints, often show joint affections, which greatly resemble arthritis deformans, followed at times by a true atrophy of the bones. These conditions have to be referred to leprous neuritis.

Presentation of Pathologic Specimens

Interesting demonstrations were given at the closing of the session. Specimens of the bacilli of leprosy in the tissues were exhibited from the laboratory of Unna, at Hamburg. Dr. Arning exhibited several specimens of leprous pathologic alteration in the nerves. It seems that the Gram method with diluted stain and continued for from 24 to 48 hours has given the best results in finding the bacilli. Dr. Goodhue, of Hawaii, exhibited lantern slides showing the pathologic alterations of the bones in leprosy.

Prophylaxis of Leprosy

Dr. Holmbae, Christiania, Norway, spoke on the fight against leprosy in a general way.

Dr. Wise, Washington, D. C., directed attention to the fact that in the countries where leprosy has disappeared or has greatly diminished there has been an elevation of the standard of living among the masses of the people. He emphasized the necessity of segregation of the lepers and strict laws forbidding immigration of leprous subjects, in order to prevent the establishment of new foci of the disease.

The following resolutions were proposed and, with the exception of No. 5, were unanimously adopted:

1. The Second International Scientific Conference on Leprosy confirms in every respect the resolutions adopted by the First International Conference, at Berlin, in 1897. Leprosy is a disease which is contagious from person to person, whatever may be the method by which this contagion is effected. Every country,in whatever latitude it is situated, is within the range of possible infection by leprosy, and may, therefore, usefully undertake measures to protect itself.
2. In view of the success obtained in Germany, Iceland, Norway and Sweden, it is desirable that these countries should isolate lepers, placing them under such conditions of life as can be voluntarily accepted by them.
3. It is desirable that the children of lepers should be separated from their parents as soon as possible, and that they should remain under observation.
4. An examination should be made from time to time of those having lived with lepers by a physician having special knowledge.
5. All theories on the etiology and the mode of propagation of leprosy should be carefully examined to ascertain if they accord with our knowledge of the nature and the biology of the bacillus of leprosy. It is desirable that the question of transmissibility of leprosy by blood-sucking insects, bugs, fleas, etc., should be elucidated and that the possibility of leproid disease among animals (rats) should receive early study.
6. The clinical study of leprosy induces the belief that it is not incurable. We do not at present possess a certain cure. It is desirable, therefore, to continue the search for a specific remedy with the greatest zeal.

The Next Conference

Professor Kobler, in the name of the Austrian Government, invited the conference to meet in Bosnia. The invitation was accepted, but the place was not decided. It has been left to the international committee to decide the time of the conference, which they must call three years before. In the same way the place has to be left to the choice of the same committee.

Hospitals for Lepers

It is of interest to report briefly visits to the leprosy hospitals.

In Bergen at present are two lepers' hospitals, both only for the nursing and for isolation of the lepers. Leprosy was formerly very wide-spread in Norway. This was only understood after the investigations of Dr. Danielssen in the forties. One hospital taken into use in 1857, was built and maintained by the state. In 1861 the state opened two new hospitals, one in Molde and one in Trondhjem. All expenses of nursing were paid by the state, and as most of the lepers are poor, the hospitals were soon filled; in 1860 and subsequent years between 700 and 800 lepers were housed in these hospitals.

INTERNATIONAL CONFERENCE ON LEPROSY

(Held in Bergen, Norway, Aug. 16-19, 1909)

(Continued from page 1046)

Transmission of Leprosy

Dr. Dehio, of Dorpat, Russia, maintained very emphatically the contagiousness of leprosy. Ehlers, of Copenhagen, referred to his experiments with parasitory human in sects which have been considered capable of spreading this disease, especially pulex and cimex lectularius, but he was not able to come to any determined conclusion. Dr. Sand of Trondhjem, Norway, in his thirty-five years' experience in the leprosarium of that city, having treated 1,558 lepers, has come to the conclusion that leprosy is not transmitted by immediate contact.

Dr. V. Dühring, Dresden, discussed hereditary transmission of leprosy. He has found that the disease affects the descendants so far as to deteriorate the race. The offspring of lepers are more subject to mortality, and, moreover, they show a disposition to acquire with infectious diseases, as tuberculosis. The transmission of leprosy from parents to children biologically and clinically is in no way probable. The direct transmission of leprosy to the fetus *in utero*, although theoretically possible, has never been proved.

Psychoses of Lepers

Dr. Moreina, of Rio de Janeiro, called attention to the psychoses of the lepers. He believes that in lepers there is no peculiar kind of insanity. Only the polyneuritic leprosy can be accompanied by the whole syndrome of Korsakow. At the onset of the disease not often can be found any kind of mental alienations. In many cases complications of leprosy, as tuberculosis, streptococcus infections, or arteriosclerosis may be cause of mental trouble in the lepers. The ordinary mental condition of the patients affected with leprosy is different and is greatly influenced by the duration of the disease, by the age, by education and the clinical forms of the disease.

Mental Disturbances in Leprosy

Professor de Beurmann, Paris, discussed the mental troubles in leprosy and the psychism of the lepers. He called attention to the mental condition of the lepers in the extreme East, which is far different from that of the Europeans. The Hindoos, the Malays and the Mongolians, although blind, mutilated and in the most terrible general condition, never show signs of mental trouble. In Asiatic asylums have been found lepers jovial and satisfied with their condition. In consequence, the sadness and the despondency of the European lepers is more due to their education and to the consciousness of having a disease of hopeless prognosis.

Treatment

The meeting on Wednesday, August 18, was devoted entirely to therapy. Dr. von Deycke, of Hamburg, discussed nastin injections. Nastin is obtained as a neutral grease from the culture of a kind of streptothrix and it seems to be identical with the neutral fat obtained from the tubercle bacillus. This so-called streptothrix has been called *streptothrix leproides*, but has no other relation to the true leprosy bacillus than to contain a kind of nastin fat. The pure nastin has the ability to produce in some of the lepers more or less reaction of general or of local nature. The reaction is subject to the greatest oscillation. While some patients are absolutely refractory to its action, others show symptoms of so severe a nature as to jeopardize life. For these reasons nastin alone cannot be used in the treatment of leprosy. When nastin is mixed with such substances which *in vitro* remove the grease from acid-fast bacilli, like tubercle bacilli, then we obtain a preparation, which can be used as therapeutic means. One preparation is nastin-B., which is nastin combined with benzoyl chlorid in an oily solution. According to the degree of concentration, nastin-B. does not usually produce a very intense reaction, and can be obtained in a form which will not cause any reaction at all. Although nastin-B. is therapeutically much more sure and constant in its action than pure nastin, yet in individual cases it shows different action. Nastin-B. acts directly on the specific cause of leprosy in the sense of bacteriolysis, as it prepares the bacilli, by removing their fat, to be susceptible to bacteriolysis. In a large percentage of lepers treated with nastin-B. improvement has followed in the general feeling. Moreover, it seems that it has prevented the farther progress of the leprous process. The nastin treatment has to be continued for one year, in form of an intermittent therapy just as it is used in syphilis.

Treatment of Ophthalmic Diseases in Lepers

Dr. Lyder Barthen, Trondhjem, Norway, spoke first on treatment of non-leprous diseases in leprous eyes, then on the genuine leprous diseases of the eyes, finally the last stages of the leprous eye diseases and their treatment.

Nastin Treatment in Russia

Dr. E. Kiwull, Wenden, Livonia, Russia, spoke on his experience with nastin treatment in the leprosarium of Wenden. He had used only nastin-B. The injections although painful were well-borne. After the injection only an increase in the temperature occurred. In the symptoms during the treatment some better and some worse could be found. Frequently ulceration occurred of old infiltrations in tubercules and in scars. In several cases swelling and pains occurred in the ulnar nerve and its ramifications. It was often remarked that hard tubercles imbedded in the depth of the skin disappeared under its action leaving only a slight pigmentation. Ulcerations of the hard palate become much more flat and showed a tendency to heal up. Examination of the blood showed that nastin increased the number of leucocytes.

Nastin Treatment in Australia

Dr. J. Ashburton Thompson, Sidney, is greatly opposed to the use of nastin. He employed the injections in 5 selected cases: 4 of tuberculous leprosy and 1 of pure leprosy of the nerves. He continued the treatment for from 6 to 9 months. In 3 of the patients the disease remained as it was. In the nervous case, the pains increased. A child became much worse. He claims that nastin is an inert substance with some irritant and also caustic effects on the seat of injection. In none of the patients did the injection produce any local reaction, or any fever.

Treatment of Leprosy

Dr. H. P. Lie, Bergen, Norway, maintained that the nastin treatment is in no way a specific treatment, and the reactive symptoms produced by the injections of nastin in the lepers is nothing but a reaction which follows the injection of any fatty substance from acid-fast bacilli. The same action is found in patients affected with tuberculosis. It is necessary to be very careful with nastin, which in patients with a tendency to tuberculosis shows a detrimental action. He considers the nastin treatment, however, as a step forward toward the betterment of this disease. He spoke of good results obtained with the method of Unna, and also from other treatments, but at the end showed a patient who for 12 years had suffered severe symptoms of leprosy and for the last eight years has shown no symptoms whatever. The patient can be considered practically well, and yet the treatment was entirely expectant.

Present Knowledge of the Lepra Bacillus

Dr. J. M. H. Macleod, London, England: The researches of the last 12 years have more firmly established the lepra bacillus of Hansen as the specific cause of this disease. By special staining methods, it is possible to distinguish the young, old and dead bacilli and the contained fat. By these methods it has been shown that the majority of the bacilli found in the tissues are dead. The finding of a cladothrix arrangement and branching forms like actinomyces, suggest that the lepra bacilli belong to the class of the streptotrix. No medium has so far been found on which lepra bacilli can be cultivated, nor is there any proof that the bacilli can live as saprophytes on decayed organic matter, decayed fish, etc. No lower animals have been found susceptible to leprosy. The presence of bacilli in gnats and bed-bugs suspected of disseminating the disease is still doubtful. The way of entrance of the bacilli into the organism is still obscure; it may be by the nasal mucosa and the upper respiratory tract, or the infection may be from the alimentary tract, or through the genitals; perhaps through the skin.

So far there is no clear idea concerning the relation of maculo-anesthetic and nodular leprosy. May it be due to the quantity of bacilli which cause nodular leprosy, due probably to racial peculiarity, climatic condition and absence of hereditary or acquired immunity. It may also be due to a qualitative difference in the virulence of the bacilli. The pathologic lesions produced in the tissues by the direct or indirect action of the bacilli are the production of the infective granuloma. In the beginning, the bacilli are outside of the cells, but later many gain entrance and multiply therein. Obscurity still surrounds the cells which may be connective-tissue cells or plasma cells containing bacilli, or may be clusters of *bacilli around a nucleus or a lymphocyte*, or may be masses of bacilli accumulated in lympatic spaces. In skin lesions, the bacilli are found in the corium, but may be present in the epidermis and in the surface of the skin. Not yet clear is the manner in which the bacilli reach the surface, it is possible that they pass through the interepithelial lymphatics, or by the sweat or through the epithelial cells, and from without being deposited by the nasal discharge or by the sputum. Not much has been added to the knowledge of visceral leprosy. In the spleen true leprous infiltration occurs, and also in the lungs, where caseation and necrosis are often found. Bacilli have been found in the glomeruli of the kidneys, in the epithelium of the uriniferous canals, but not in the urine. The genitals, ovaries and testicles have been found extensively affected with leprosy, but yet the bacilli have never been found in the Graffian follicles, in the seminiferous tubules, or in the semen. Bacilli have been found in the blood, but as it has been taken from the lepromata it may be that bacilli were taken from the lymph. The blood shows all characteristics of anemia with a slight eosinophilia.

Leprosy of the eye is a late manifestation of nodular leprosy, only rarely primary. It is possible that the infection takes place in consequence of the general infection as the chorioid is the chief site of the disease and the cornea is involved after the deeper parts. It is also possible that the infection takes place from without, the conjunction being infected first, then the cornea, corneosclerotic limbus, ciliary body and finally the uveal tract. Diversity of opinion is found in reference to the pathogenesis of maculo-anesthetic leprosy. It has not yet been decided whether the maculo-anesthetic lesions are identical with those of the nodules, and have to be considered as an early stage of the skin lesion, or whether they are to be considered as a form of inflammatory process of the type of erythema persistans. Peripheral nerves may be affected in all forms of leprosy, but more markedly in the maculo-anesthetic type. The presence of the bacilli and of their toxins leads to neuritis and interstitial proliferative alterations, which by pressure on the vital nerve tissue cause degeneration of the axis cylinder. It seems that the neuritis so produced causes eventual destruction of the bacilli and consequently leprosy of the nerves is self-curative. It is doubtful if the spinal cord and the ganglia are affected by the bacilli, and it is also possible that the changes which take place in the posterior columns of the cord are not due to the bacillus *in situ*. These changes are not characteristic, and resemble the changes following the ascending degeneration of a peripheral nerve from injury or as the results of general cachexia. The possibility of the association of leprosy with other diseases as tuberculosis, syphilis, etc., must not be forgotten, and the ravages of these associated diseases must not be attributed to leprosy.

Blood Reactions in Lepers

Dr. Babes, Bucharest, spoke on the reactions of the blood in the lepers; it seems that there is nothing specific to give much light on the subject.

Dr. George Meyer, Berlin, maintained that the lepra serum gives the same reaction as the serum in syphilis, only in cases of the tuberculous type.

Bone and Joint Changes in Leprosy

Professor Harbitz, Christiania, Norway, spoke on the leprous alteration of the bones and joints from trophoneurotic causes. The hands and the feet, especially at the tarsal and carpal joints, often show joint affections, which greatly resemble arthritis deformans, followed at times by a true atrophy of the bones. These conditions have to be referred to leprous neuritis.

Presentation of Pathologic Specimens

Interesting demonstrations were given at the closing of the session. Specimens of the bacilli of leprosy in the tissues were exhibited from the laboratory of Unna, at Hamburg. Dr. Arning exhibited several specimens of leprous pathologic alteration in the nerves. It seems that the Gram method with diluted stain and continued for from 24 to 48 hours has given the best results in finding the bacilli. Dr. Goodhue, of Hawaii, exhibited lantern slides showing the pathologic alterations of the bones in leprosy.

Prophylaxis of Leprosy

Dr. Holmbae, Christiania, Norway, spoke on the fight against leprosy in a general way.

Dr. Wise, Washington, D. C., directed attention to the fact that in the countries where leprosy has disappeared or has greatly diminished there has been an elevation of the standard of living among the masses of the people. He emphasized the necessity of segregation of the lepers and strict laws forbidding immigration of leprous subjects, in order to prevent the establishment of new foci of the disease.

The following resolutions were proposed and, with the exception of No. 5, were unanimously adopted:

1. The Second International Scientific Conference on Leprosy confirms in every respect the resolutions adopted by the First International Conference, at Berlin, in 1897. Leprosy is a disease which is contagious from person to person, whatever may be the method by which this contagion is effected. Every country, in whatever latitude it is situated, is within the range of possible infection by leprosy, and may, therefore, usefully undertake measures to protect itself.

2. In view of the success obtained in Germany, Iceland, Norway and Sweden, it is desirable that these countries should isolate lepers, placing them under such conditions of life as can be voluntarily accepted by them

3. It is desirable that the children of lepers should be separated from their parents as soon as possible, and that they should remain under observation.

4. An examination should be made from time to time of those having lived with *lepers by a physician having special knowledge.*

5. All theories on the etiology and the mode of propagation of leprosy should be carefully examined to ascertain if they accord with our knowledge of the nature and the biology of the bacillus of leprosy. It is desirable that the question of transmissibility of leprosy by blood-sucking insects, bugs, fleas, etc., should be elucidated and that the possibility of leproid disease among animals (rats) should receive early study.

6. The clinical study of leprosy induces the belief that it is not incurable. We do not at present possess a certain cure. It is desirable, therefore, to continue the search for a specific remedy with the greatest zeal

The Next Conference

Professor Kobler, in the name of the Austrian Government, invited the conference to meet in Bosnia. The invitation was accepted, but the place was not decided. It has been left to the international committee to decide the time of the conference, which they must call three years before. In the same way the place has to be left to the choice of the same committee.

Hospitals for Lepers

It is of interest to report briefly visits to the leprosy hospitals.

In Bergen at present are two lepers' hospitals, both only for the nursing and for isolation of the lepers. Leprosy was formerly very wide-spread in Norway. This was only understood after the investigations of Dr. Danielssen in the forties. One hospital taken into use in 1857, was built and maintained by the state. In 1861 the state opened two new hospitals, one in Molde and one in Trondhjem. All expenses of nursing were paid by the state, and as most of the lepers are poor, the hospitals were soon filled; in 1860 and subsequent years between 700 and 800 lepers were housed in these hospitals.

The results of these measures were very beneficial and while in 1865 there were 2,870 lepers in Norway, there are now only about 400.

There is no more need for so many hospitals, therefore, the one at Molde has been converted into a tuberculosis hospital. In St. Joergen's hospital in Bergen there are at present 29 patients; no new patients are admitted, so that when those now living there die, the hospital will be abolished. St. Joergen's had its own property, acquired in earlier ages by the levying of a tax on every farm in the province of N. Bergenhus.

In the other hospital at Bergen are housed at present 84 patients. They are visited daily by Dr. Lie and Dr. Rückner, who give them the most scientific and the most charitable treatment. There are usually four patients in each room. The rooms are spacious and well aired. All forms of the disease can be seen. Most of the patients have suffered contraction of the fingers with that resulting characteristic deformity of the hand. Many have their fingers, hands and feet badly mutilated. In many cases lesions of the feet, knees, and nose, have caused extended and deep ulcerations, which are daily washed with boracic-acid solution and dressed with iodoform gauze. In many patients the eyes have been destroyed; and in a great many the nose has been entirely destroyed. In some the mouth has been reduced to a small deformed hole, which scarcely permits the introduction of food. In many cases the tongue showed lepra tubercles, mostly at its edges. Nearly every patient has leucoderma of the arms and of the legs in form of deep whitish spots, surrounded by deeply pigmented edges.

In one case of lepra tuberosa in a man, the face was so full of tubercles that his features had entirely disappeared. In a woman with a form of lepra maculosa, deeply red erythematous spots covered the neck, chest, shoulders, arms and legs. The spots were somewhat raised at the edges, brilliant, glossy and somewhat hard. Some of her fingers were somewhat swollen, but the hands were not yet contracted. Many patients were suffering with muscular and arthritic pains, and neuralgic pains.

In the men's department there is a large room where the patients work as cabinet makers. In the women's department those who can work are spinning, knitting, etc. In this way the patients may earn a little money, which they are allowed to keep.

It might be thought that the articles manufactured in the hospital would have been of danger to other people, but during all the years the hospital has existed and the people in town have bought articles made there, not a single instance is known of leprosy having spread from the hospital, not even in the years when it was not thought that the disease was infectious and, therefore, no cleansing of the articles made in the hospital was done, as it is practised at present. No one is allowed in the hospital except medical men.

Conditions in the United States

It may be of some interest to refer to conditions in the United States. The statistical dates are taken from Dr. H. P. Lie's paper. The official statistics of the commission of United States Public Health and Marine-Hospital Service gave the number of lepers in 1902 as 278, 145 of which were born in the United States. Foreign born individuals affected with leprosy in the United States are represented as follows:

Norwegians	22	From the Antilles	4
Icelanders	11	Mexicans	3
Swedish	8	Irish	6
Chinese	20	English	3
Japanese	1	French	3
Germans	12	Italians	4
Bohemians	12	Spaniards	1
Cubans	6	Australians	3

Of this number only 72 lepers are segregated. The forms of leprosy in the United States can be divided as follows: Anesthetic, 107; tuberculous, 88; mixed, 56. In California, San Francisco has 18 cases of leprosy. Of the 24 cases reported in this state, 11 patients are Chinese, but 7 of them have acquired the disease in the United States. The 11 Icelanders are settled in North Dakota and it seems that all contracted the disease in Iceland. Minnesota is the preferred state for the Scandinavians, of which 4 from Sweden and 16 from Norway affected with leprosy have established their home. Armauer Hansen in 1900 remarked that 287 lepers had left Norway and that 170 had emigrated to the United States. But only in 30 had the disease showed manifest signs before they left their native country. Bracken has found in Minnesota, 5 Swedes and 6 Norwegians affected with the leprosy. He believes that in the United States there are 160 lepers of Scandinavian origin scattered in Minnesota, Wisconsin, Iowa and South and North Dakota.

Twenty-four lepers are reported to be in Florida, of which 12 are Bohemians, 6 are Cubans and 5 are Americans.

Isadore Dyer, who is so interestingly connected with the history of this disease in the United States, maintains that leprosy was introduced in Louisiana from the Antilles about 1776. The leprosarium of Indian Camp has received since 1894, 80 lepers, of which 38 are still living, 37 are dead and 5 ran away from the asylum.

Morrow in 1899 and James N. Hyde in 1894, have tried to determine the number of lepers in the United States. It can be stated that lepers in the States of the Union can be at present considered as 278. The danger is mostly in the immigration.

The disease is too horrible for the government to wait before taking any prophylactic step. The disease is obscure and treacherous, and the lepers try to conceal it. Physicians who have had no special training in this disease are frequently unable to recognize leprosy. Leprosy must be considered contagious and as such reported to the health officer of the state. The reported leper should be examined by a specialist, and when the disease is definitely diagnosed should be segregated in a government colony.

MEDICAL SOCIETY OF THE MISSOURI VALLEY

Twenty-second Annual Meeting, held at Council Bluffs, Iowa, Sept. 9-10, 1909

(Concluded from page 1049)

Unrecognized Gall-Stone Disease

DR. DANIEL MORTON, St. Joseph, Mo.: In this paper I discuss neuralgia of the stomach, biliousness, autointoxication, nervous symptoms, pain in the gall-bladder, referred pain, vomiting, colic, tumor, jaundice, gall-stones and cancer of the gall-bladder. Let us not be deceived with the belief that gall-stones represent the final stage of gall-stone disease. It is now conceded and statistics prove that the frequent concurrence of gall-stones and malignant disease is not accidental, but that the former by their irritation produce the latter. I mention this fact in order that I may emphasize the necessity for early recognition of gall-stone disease. Courvoisier found 72 cases with gall-stones in 84 cases of primary gall-bladder cancer. Possibly, the inaugural symptoms of gall-stone disease may be best brought to the attention of general practitioners by stating that cases of "indigestion," "biliousness," "neuralgia of the stomach," "gastralgia" and "autointoxication" are, in the majority of cases, in reality, cholecystitis, and should be recognized and treated as such. The diagnosis can usually be confirmed by a physical examination of the gall-bladder and a search for the pressure pain points described. The symptoms which heretofore have been considered inaugural, for instance, stone colic and jaundice, are really terminal and are found only after the disease has been long existent and indicate a late stage of the disease.

Our knowledge of cholecystitis is increasing rapidly not only as a pathologic condition affecting the gall-bladder alone, but also affecting the liver itself and the pancreas. We are also discovering that the stomach is a much maligned organ and that it has heretofore been charged with offenses of which it was guiltless and for which its nearby neighbor, the gall-bladder, has been proved responsible. In a word the gall-bladder as an important factor in the causation of trouble in the organs adjacent is assuming a rapidly increasing important rôle. In the beginning of gall-bladder surgery attention was directed to the organ itself and it was made the objective point of all surgical measures. But it was found that with the relief of the pathologic condition in the gall-bladder not only was the original purpose, for which the operation was done accomplished, but in addition, over and above this, symptoms disappeared which had formerly been attributed to other organs. Putting operative findings and clinical together, therefore, a number of obscure abdominal disturbances are coming out of the darkness of ignorance into the light of scientific knowledge.

DISCUSSION

Dr. John Monroe Bannister, Omaha: I would like to relate my experience in the Philippine's, in reference to this line of work. Conditions of extreme congestion of the liver and enlargement are not found in the United States as they are in the tropics; consequently a diagnosis of enlarged gall-bladder is easy. While in the Philippines, I did a large amount of surgical work. There were many cases of liver disease to treat, and in the number of patients operated on there was not a single case of disease of the gall-bladder. Frequently disease of the gall-bladder was suspected, but in these cases the livers would be so enlarged from passive or active congestion as to fill the abdominal cavity. It was a rule in suspicious cases to perform laparotomy as a routine measure, going in, getting the enlarged liver out of the way, exploring and examining the gall-bladder to see if there was anything the matter with it. It was found that the livers of these patients were very much congested and enlarged. It was also a rule to aspirate the liver and if an abscess was not found a good deal of blood was drawn off; but these patients invariably did well.

Dr. A. I. McKinnon, Lincoln, Neb.: It is possible to have biliary or gall-stone colic without the presence of gall-stones. Gall-stones are due ordinarily to infection. Cholecystitis frequently accompanies infectious diseases, and many times the trouble begins in childhood, following some infectious disease. When there is an acute cholecystitis, for instance, complicated with pneumonia, there is jaundice, and as the growth of fibrous tissue replaces the exudate, contraction takes place, and obstruction to the bile tracts occurs.

Dr. A. B. Somers, Omaha: The removal of the gall-stones does not always relieve or cure the primary condition which still exists, and the patient should be taught to go to a physician when he gets through with the surgeon, unless the surgeon is also a physician.

Dr. W. F. Milroy, Omaha: I want to go one step further than the last speaker, and say that these patients should go to see a physician before consulting a surgeon, as I am firmly convinced that most of these individuals can be cured by medical treatment and require no operation whatever.

Surgical Suggestions for the Treatment of Chronic Appendicitis

Dr. A. I. McKinnon, Lincoln, Nebr.: In this paper I recommend that the incision be made high enough for examination of the upper abdomen and treatment of those parts which may be found involved. This incision can be made about the same as a gall-bladder incision, the lower end being even with the umbilicus, or at a point where most authorized incisions begin. Through such an opening, the appendix can be easily pulled up and with the aid of a proper position of the patient the whole abdomen and pelvis will be open for examination. For further faciliating this exploration, I advocate the sitting posture of the patient. This not only allows complete exploration, but permits it to be done through a small incision. I have used this posture for several years with great success in handling the abdominal viscera. Chronic appendicitis often either complicates or is complicated by a pathologic condition of the upper abdomen, which, if overlooked, will lead to continued trouble on the part of both patient and surgeon.

Scientific Feeding

Dr. Minda A. McLintock, Atchison, Kans.: Man is said to be the net product of what he eats and drinks. Food bears the same relation to him that soil does to vegetation. No man can be at his best physically who is underfed. A celebrated chemist says: "If we could ascertain perfectly the demands of the human body and supply perfectly those demands, life might be prolonged indefinitely." He enjoys the best health, the keenest mentality, the high physical powers, who can select for himself those articles of diet that will most nearly supply all the constituent parts of the body in natural proportions. To do this: First, food must contain all the nutritive elements the body requires. Second, only such foods must be combined at each meal as will produce chemical harmony in the stomach. Third, food must be proportioned so that the body will not be overfed with certain elements of nutrition and underfed with others. No less important is the observance of natural laws or idiosyncrasies, namely, age, sex, temperament, environment, together with the season of the year, occupation, exercise, etc.

The Bacteriologic Diagnosis of Epidemic Cerebrospinal Meningitis

Dr. S. R. Hopkins, Omaha: I wish to present a brief and practical method of establishing a bacteriologic diagnosis in this affection. A Gram-negative diplococcus occurs most often in the interior of the leucocytes of the spinal fluid. There are six species of Gram-negative diplococci with which it is possible to confuse the diplococcus of Weichselbaum, and chief among these are the diplococcus of gonorrhea and the so-called pseudomeningococcus. For practical purposes, however, the identification of the meningococcus in the spinal fluid withdrawn by lumbar puncture from a patient presenting phenomena suggesting meningitis, is a procedure fraught with little difficulty, and it is the only means of affirming a positive diagnosis. In staining by the method of Gram it is well to finish the staining process by flooding the slide with a 0.25 per cent. solution of eosin in water, thus giving to the Gram-negative bacteria a red color. In order to establish a certain bacteriologic diagnosis one should in every instance resort to cultivation of the germs on artificial media, and in this connection I wish to state that I have never encountered the slightest difficulty in obtaining a luxuriant growth of the meningococcus, by simply inoculating a slant of plain agar or blood serum, with the infected spinal fluid, and this, in from eighteen to twenty-four hours. In inoculating the artificial culture media, it is necessary that the inoculation be made very soon after the withdrawal of the fluid, as the germs are short-lived outside of the body and show little resistance to drying. The growth on blood serum is more abundant than on agar and it does not liquefy it. The growth appears as white, glistening spots which rapidly coalesce. The organisms do not live long on the media, and if one would keep a culture for any time it is necessary to reinoculate other tubes at least every forty-eight hours.

Advantage of Cholecystostomy in Draining the Deeper Biliary Tracts

Dr. H. G. Welpton, Des Moines, Iowa: This paper was suggested by a serious and unexpected complication that attended two cases of cholecystectomy in my practice. The cases were of the simple type, without adhesions, obstruction, or destructive changes. The gall-bladder was removed with much the same assurance of a cure as we have when we remove an infected appendix. In one of the cases a large calculus formed with the hepatic duct above an acute angulation of the common duct. The angulation was due to an adhesion to the colon. In the other an acute exacerbation of a chronic pancreatitis came on at intervals obstructing the common duct. My patients were only partially relieved by removing the stone, by releasing the adhesions, and by drainage. Since reviewing the literature, I have limited cholecystectomy to those cases in which either the gall-bladder or cystic duct has been contracted or obstructed, or in which an irreparable damage from gangrene, infection, ulceration perforation or malignancy has occurred. I prefer to leave the gall-bladder, when possible, since excision does not remove the infection that is in the common and biliary ducts. I believe from my clinical, pathologic and bacteriologic findings that the common and biliary ducts partake of the infection of the gall-bladder in every case to a greater or less degree. Gall-bladder drainage offers the best means of a complete cure of the infections of the deeper tracts as well as those of liver and pancreas. It also provides for a cholecystenterostomy in case of complete obstruction, and serves as a guide to the deeper structures. In cases in which later calculi reform, or partial obstruction develops, cholecystenterostomy will prove a happy solution of these complications.

Diagnosis and Treatment of Stricture

Dr. A. C. Stokes, Omaha: In this paper I summarize the treatment of stricture of the urethra as follows: 1. Alkalies, diluents, and rest are serviceable in most cases of strictures—sometimes indispensable if there be any serious complications. 2. All uncomplicated strictures, not highly irritable or resilient, should be treated by dilatation with soft instruments up to No. 15 French, and with conical steel sounds afterward; reintroductions being made every third or fourth day. 3. Until well acquainted with the temper of a given stricture, every sounding should be preceded by hexamethyelenamin, followed by nitrate of silver. 4. Dilatation need rarely be carried beyond the caliber of the normal meatus. 5. Any stricture resisting dilatation must be cut. 6. For the pendulous urethra do internal urethrotomy; for the perineal urethra do external urethrotomy or the combined operation. 7. In general, anterior stricture of the urethra is curable; deep stricture of the urethra incurable. 8. Impassable strictures without retention may usually be overcome with whalebone bougies by time, patience and skill. If they finally proved impassable, the treatment is external perineal urethrotomy. 9. Retention is treated by hot baths, ether, opium, tincture of the sequichlorid of iron; failing these, by aspiration, or by external urethrotomy without a guide. 10. Traumatic stricture may be prevented by section at the time of injury. Once having shown itself, it usually requires excision for a cure. 11. Resilient and nodular strictures are best treated by excision. 12. Irritable strictures may often be cured without cutting.

Does the Present Conservatism in Pelvic Surgery Serve the Best Interest of the Patient?

Dr. Bernard A. McDermott, Omaha: Summing up the literature I find that it gives widely divergent views as to the relative value of conservatism in pelvic surgery. But whether we advocate conservatism or radicalism in pelvic operations our object should be the same—namely, the relief of existing conditions. If in this we fail, the operation has been a failure. My experience makes me oppose conservatism or any plastic work in certain pelvic lesions, such as a partially diseased tube or ovary. In the latter condition, the resection of a cystic or partially diseased ovary, as a routine procedure, it is to be mentioned only to be condemned, as the cutting and plastic work necessary to such an operation usually produce more postoperative pain tenderness and general symptomatology than would the original condition. I have seen this follow so many times that I am convinced that, if there is any real reason for saving the ovary other than conservatism of ovarian tissue, it is far better for the patient to remove the entire organ or leave it entire. Most operators leave one or both ovaries after hysterectomy for a non-malignant condition, stating that the menopause is much milder and the woman is better off in every way. Granted that the menopause may not be so acutely ushered in when the ovaries are left; but does not the condition last indefinitely? Is it not better for the woman to have the symptoms early? Though acute, they will be brief. Again, in uteri containing multiple fibroids, is it not better as a routine procedure to do a supravaginal hysterectomy than myomectomy?

Kreissl, Chicago; "The Objects of Mechanical and Surgical Treatment of Infantile Paralysis," by Dr. H. Winnett Orr, Lincoln, Nebr.

SIXTEENTH INTERNATIONAL MEDICAL CONGRESS

Held at Budapest, Aug. 29—Sept. 4, 1909

(Continued from page 1045)

Treatment of Diffuse Free Progressive Peritonitis

Dr. Arpad G. Gerster, New York: The basis of this report is formed by 609 cases of the malady, observed at Mount Sinai Hospital during about ten years. Of these, 461 were caused by the appendix (out of a total of 3,144 cases of appendicitis) and 148 were due to injuries and affections of other viscera. Difficulties surround the making of a precise diagnosis and estimation of prognosis in peritonitis. To uncertainties dependent on these difficulties in establishing a uniform and reliable nomenclature of the disease may be ascribed the small value to be placed on statistics. In accepting the diagnosis of free progressive peritonitis very strict criteria must be insisted on; and even with these statistics have only a relative value. Every patient with appendicitis and *a fortiori*, every patient with peritonitis, in whatever stage of the malady they may present themselves to the surgeon, ought to be operated on without delay, except moribund patients. The arguments by which the advice is supported, not to operate on "intermediate" cases of appendicitis on account of the high mortality, are fallacious. A tabulated *résumé* of the results of operative treatment in 461 cases of diffuse, free, progressive peritonitis, due to appendicitis, shows a steady decline of mortality from 79 per cent. in 1899 to 14 per cent. in 1908. This improvement is ascribed to the abandonment of heroic and incisive measures in cleansing of pus and in drainage of the peritoneum, which were in vogue in 1899, and the adoption of early, simple, rapid and less exhausting operative procedures, complemented by Fowler's posture and Murphy's proctoclysis. Of complications, the most common, observed in 9.3 per cent. cases, was that of secondary intraperitoneal abscess. This may be regarded as a residual manifestation of a primarily general process. Mechanical ileus, rather frequent (158 per cent.) in 1899, has become much rarer (5.4 per cent.) since the abandoning of the use of extensive gauze packings. My procedure is as follows: (1) Preliminary lavage of the stomach; (2) anesthesia by nitrous-oxid gas followed by ether; (3) rapid exposure of primary focus of infection; (4) stoppage of visceral leak by suture or tamponade; (5) gentleness and rapidity of procedure, avoidance of friction by wiping, etc.; (6) no irrigation; (7) soft rubber-tube drainage of right iliac fossa and, if necessary, of Douglas's pouch; (8) closure of external wound by three layers of suture; (9) for paralytic ileus repeated gastric lavage, low and high enemata, or systematic rectal lavage, enterotomy by stab done in intractable cases only; (10) rational administration of opiates; (11) withholding of all ingesta while vomiting is present; (12) Murphy's proctoclysis; (13) Fowler's position; (14) early incision and drainage of secondary abscesses; (15) laxatives, calomel and salts, to be given only after cessation of vomiting; and (16) tampons used for walling off necrosed areas not to be disturbed without necessity till they become detached of themselves.

Diagnosis of Laryngeal Cancer

Sir Felix Semon, London, Eng., described cases of malignant disease in which exceptional diagnostic difficulties were encountered and diagnostic mistakes made. They amounted to 13 in a total number of 246 cases of malignant disease seen in 33 years' practice, and after faithfully recording the salient features of each of them, he exhorted his younger *confrères* not to consider the early diagnosis of malignant disease of the larynx as exceedingly difficult, but to keep in mind the following unusual features present in the series of cases reported: 1. Malignant disease of the larynx, appearing first in the form of a curious tumefaction of the left vocal cord, which remained stationary for nearly two years before showing its true nature. 2. Chronic infective inflammation, simulating malignant disease of the larynx. Extravasation of blood into the right vocal cord and below it, simulating malignant disease of the larynx. 4. Laryngeal tuberculosis in which the laryngoscopic appearances left the diagnosis between malignant disease and tuberculosis quite undecided. 5. Laryngeal tuberculosis simulating malignant disease in a man aged 70 years. 6. Tuberculous tumor, simulating malignant disease, in the anterior commissure of the vocal cords. 7. Leucoma of a vocal cord, simulating malignant disease of the larynx. 8. Epithelioma of the left ventricle of Morgagni, at first mistaken for papilloma. 9. Epithelioma originating in the form of an angioma. 10. Papilloma, occupying the whole posterior part of the right vocal cord and the inner aspect of the right arytenoid cartilage in a man aged 60, mistaken for malignant disease of the larynx. 11. Epithelioma of the larynx appearing in the form of a snow-white, sharply pointed "meadow." 12. Granuloma originating in the scar due to removal of an epitheliomatous tumor of the right vocal cord. 13. Inflamed papilloma in a man, aged 60 years, closely simulating the appearance of an epithelioma of the larynx.

Adenoid Growths

Dr. Citelli, Catania, Sicily, after referring in his historical remarks to the great merit of Meyer in making known to the scientific world such a frequent and important disease, recorded briefly the normal and pathologic anatomy of the tonsil, founded also on extensive researches of his own.

In order to be able to determine with some exactness whether a tonsil is to be considered as normal or as hypertrophied—an indispensable decision for investigators undertaking the study of the tonsil—a thorough knowledge is required of the normal evolution of the tonsil in man. The tonsils are of use during early infancy as hematopoietic organs, and besides this as organs of defense against infection. In view of their position they may also serve as a means of exit for infection, and in some cases, when the defensive elements are not sufficient for their purpose, as a means of ingress. It is not probable that the tonsils belong to the so-called organs for internal secretion, but in view of certain general or secondary disturbances which are found in adenoid-bearing subjects, and which often disappear after an operation, and, more especially on account of anatomic researches I believe it probable that the hypertrophy of the tonsil alone can determine, first the functional, and then the anatomic, alterations of the pharynx and central hypophysis. The causes of this disease may be congenital or acquired; these latter, however, will only provoke the growth of adenoids in predisposed subjects. Adenoid symptoms may be divided into local symptoms, disturbances in nasal respiration and its relative consequences, disturbances in the other respiratory organs, vocal disturbances, uricular disturbances, etc., and general or secondary symptoms, alterations in the circlulation, psychic disturbances, exophthalmos, spasms of the larynx, night-terrors, nocturnal enuresis, nervous cough, etc. The treatment in the majority of cases is operation. Almost all the instruments designed (for the purpose) are good, in experienced hands. Adenoid growths, which can exert a great influence over the physical or psychological development of individuals, and hence the great utility of making such a disease and its consequences known to the public.

Present State of the Knowledge of the Prophylaxis of Dental Caries

Mr. Kenneth W. Goadby, London, England: The prevention of dental caries holds the same position with regard to stomatology that preventive medicine does to general medicine, and, as in preventive medicine, both preventive measures and treatment of the disease are essential factors. The recent developments in the appointment of qualified officers to treat dental disease in the army, navy, industrial schools, public schools, and institutions, as well as the recent development of municipal dental surgeons, are important factors in distributing knowledge. The principles laid down by stomatologists for the guidance in the prophylaxis of caries are based on a consideration of the pathology, but sometimes important questions are overlooked. In dental caries the etiology must be considered under the heading of—(a) the predisposing causes:—structure, environment, and position; (b) exciting causes:—micro-organisms and foodstuffs; and (c) contributory causes:—hygiene. In a hundred cases taken at random, 25 per cent. of the individuals had no dental caries. These were patients with suppuration of the gums and alveolar processes. The bacteria present in the mouths of all these people have been isolated and carefully tested by bacteriologic means, including fermentation of carbohydrates. It was found that in the mouths in which dental caries was not present organisms capable of fermenting lactose were less frequently present than in those in which caries was present. In mouths without caries 64 per cent. were free from lactose fermenters, while in mouths in which caries was present, or had been present and was treated, the lactose fermenters were present in 60 per cent.

Arteriosclerosis, Including Its Cardiac Form

Dr. H. Huchard, Paris: The chief points of M. Huchard's argument were the following: There exists great confusion among pathologists as to the nature and process of arteriosclerosis, so that it is impossible to give an exact and rational definition of the disorder from the pathologic side. Neither can pure experience settle the question, but the clinical evolution of arteriosclerosis affords the method of distinguishing between that disease and atheroma. Atheroma is really a senile affection, coming on in persons of from 60 to 80 years of age, and it is entirely a vascular change. Arteriosclerosis, on the other hand, attacks persons between 30 and 60 years of age and is so largely a visceral complaint that its best name is arteriovisceral sclerosis. Gull's and Sutton's conception of an "arteriocapillary fibrosis" is incomplete. There are some arterioscleroses at their outset typically aortic and which may be called myovalvular. From the triple view-point of the pathologist, the clinician, and the therapist the distinction between such endocardial valvular "cardiopathies" and the endarterial "cardiopathies" are of considerable importance. The six principal causes of the latter condition are gout and "uricemia," lead poisoning, syphilis, faulty diet, tobacco, mental strain, and overwork. There are four stages recognized clinically in the evolution of arteriosclerosis: (1) arterial presclerosis; (2) the cardioarterial stage; (3) the mitro-arterial stage; and (4) the final stage of cardiac failure. The symptoms fall under the three heads, toxic (the predominant group), cardioarterial, and renal, and each requires a special line of treatment. The beginning, the course, and the climax of the arterial cardiopathies are comprised in the word intoxication, having for its chief symptom dyspnea. Careful distinction must be made between a pathologic lesion and clinical disease. Simple atheroma may remain for a long time nothing more than an anatomic change. In cardiosclerosis, on the other hand, the subjective symptoms predominate over the physical signs which may indeed be absent, as in mitral contraction of sclerotic origin. In mitral regurgitation of similar origin the patient may be considered "a mitral case" so far as his murmur goes, but he is really "an arterial or aortic case." From the outset the renal factor is of great importance in determining the retention of the toxic substances and the increase in the arterial tension. Renal insufficiency is an early and constant symptom in arterial cardiopathies even if there be no albuminuria, and this fact accounts for the importance of renal treatment to eliminate the toxins during the whole course of the disease. Clinically cardiosclerosis can take its beginnings in the kidney, the heart, or some other organ, but there is no such thing as arteriosclerosis without both arterial and renal lesions. It may happen that cardiac lesions of rheumatic origin become complicated by arteriosclerotic changes between the ages of 30 and 50 years and a fresh train of symptoms may ensue. Asthma and emphysema only lead to stoppage of the heart through the arterial lesions which occur with them, but asystole of true gastric origin is extremely rare. The therapeutic indications are different in the four stages of the disorder, but dietetic regimen with measures directed to the renal efficiency are always the basis of sound treatment. In a disease which is above all things an intoxication, the abuse of drugs, especially of the iodids and digitalis, is to be especially avoided, and also the abuse of so-called anti-sclerotic serums, high-frequency currents, and climatic and some mineral water "cures."

The Nature of Antagonism in Bacteria and Its Practical Importance

Prof. N. Pane, Naples, Italy: Among the pathogenic microbes only the bacillus of anthrax can be destroyed in the system by the antagonistic action of several bacteria—*Streptococcus erysipelatis, Staphylococcus pyogenes, Bacillus* *pyocyaneus*, pneumococcus, and *Bacillus prodigiosus*—under special conditions. The most favorable of these conditions is the subcutaneous inoculation of anthrax mixed with one of the others in suitable doses. The particular state of virulence or non-virulence of the antagonists, and the choice of the animals for experiment are of great importance. The antagonistic action of a bacillus may meet with complete success in the animal organism, even when it fails or is only partially successful when applied to infected grazing land or when tested for on nutritive substances in the laboratory. The substance or substances which act against the bacilli of anthrax in the organism belong partly to the antagonist and partly to the antibodies in the organism itself. As regards the nature of the antagonistic substances, confining ourselves to the *Bacillus pyocyaneus*, which is the most energetic and the most certain in its action, it is to be observed that the broth culture of this bacillus, killed by exposure to a temperature of 55 C. for an hour, shows in the test-tube a bactericidal action at from 35 to 37 C. by far superior than that which is shown at 15 C., and this bactericidal action weakens considerably after heating to 100 C. for an hour. If the dry remains of the broth culture be mixed with absolute ethyl alcohol a clearly demonstrable bactericidal substance is diffused into the alcohol, although it is readily separated from the alcohol by evaporation at 60 C. The practical application of the resistance of *B. pyocyaneus* to anthrax might be made in the vaccination of animals susceptible of spontaneous infection, since a considerable immunity can be conferred on animals under experiment by means of subcutaneous inoculation with the anthrax bacillus mixed with the soluble products of *B. pyocyaneus*.

A Comparative Estimate of Pharmaceutical and Physical Agents in Therapeutics

DR. C. COLOMBO, Rome, Italy, reviewed the physiologic and therapeutic action of certain chemical and physical agents on the human body in the light of recent medical literature and of his own experiences. He considered three possible requirements of a physician in search of a special remedy. He may want to produce an effect which could be obtained equally well from a physical or a chemical agent, or an effect which could only be obtained from one or other of those agents. In the first case Dr. Colombo would always choose the physical agent for the following reasons. Such an agent constitutes an external stimulus of which the nature and effect on the body is exactly known, the effect is always the same for the same stimulus with the intensity of which it is in strict proportion. On the other hand, the chemical agent does its work inside the body in contact with the cellular fluids; it follows that however well we may understand its composition and its action *in vitro*, we remain in the dark as to its effect *in corpore* and of the resulting reaction of the organism. Dr. Colombo quoted examples of each of those three groups.

Recent Progress in the Clinical Study of the Evolution of Syphilis

DR. H. HALLOPEAU, Paris, France: When the chancre manifests an intense reaction, and the morbid products formed by it are of great virulence, it is a sign of an over-activity of the treponema. The germs given off by the chancre may take different routes. (a) They may go by the lymphaticus, which transmits them with or without lymphangitis to the neighboring lymphatic glands. (b) They may go by the capillaries. (c) They may enter the neighboring tissues where they spread. These last show a higher degree of virulence than those which later come from the lymphatic glands, for the glands possess a great power of attenuating the micro-organisms. Among the ultravirulent manifestations must be put most of the secondary manifestations of the vulva, of the prepuce, and of the parts around the anus. When the lymphatics and the lymphatic glands do not transmit the micro-organisms infection can only take place by the blood stream, and then the roseola does not appear, and, therefore, it may be said that the roseola is associated with the early affection of the lymphatic glands. The generalized infection only takes place at the beginning of the secondary stage and later the lesions are spread exclusively by intrainoculation and extrainoculation. 4. In grouped syphilides, the initial lesion often shows signs of a virulence greater than that of the lesions derived from it. On the other hand, extensive cicatricial syphilides may continue to spread with increasing outbursts, so it is clear that *the resistance of the tissues can be increased or diminished.* As the disease advances in evolution it gives rise to modifications in the intensity and the modification of the treponema, and, consequently, in the nature of the toxins produced. The pathologic action of the treponema is entirely due to the soluble substances to which it gives rise. In different subjects the treponema is prone to attack certain tissues. There are also affections liable to be produced under the influence of syphilis and later progress spontaneously, and these are the so-called syphilitic deuteropathies.

Treatment of Lupus Erythematosus

SIR MALCOLM MORRIS, London, Eng.: The disease appears to be essentially a chronic inflammation of the skin, local in origin, and depending on a condition of the circulation which makes the integument prone to vasomotor disturbance. This may cause a predisposition to toxic infection, but neither the fact of such infection nor its nature has been positively demonstrated. Each case must be dealt with according to its peculiarities. The treatment should be constitutional and local. Under the former head must be included careful regulation of the diet, so that the intestine may not be loaded with materials that may form a favorable soil for infection. Anything, like coffee and tea, which causes flushing of the face, is contraindicated. Quinin is often useful. Locally, in the hyperemic stage, cooling lotions and ointments of subacetate of lead may be prescribed. Ichthyol in the form of a lotion or an ointment is among the most useful of local remedies. In chronic cases the constant application of a strong solution of ichthyol is the best remedy, but iodin liniment is also valuable. In several conditions linear scarification or light touches of the thermocautery often gives good results. In subacute cases high-frequency currents and in chronic cases the Finsen light and the *x*-rays may be used with success. These agents are particularly useful in the later stages when there is thickening of the integument.

Medicolegal

Liability of Counties to Physicians for Expert or Other Witness Fees in Criminal Cases

The Supreme Court of Wisconsin says that the complaint in the case of Philler vs. Waukesha County evinced a purpose to state a cause of action against the county for the value of a physician's time and services in making examinations of the symptoms and mental condition of a defendant in a criminal trial, and in attending court to testify with respect to his sanity "as an expert witness," in the words of the complaint. Except for said quoted clause, there was no suggestion as to the character of the testimony he gave, whether it related to facts which he discovered by observation, albeit a trained and expert observation, or to an opinion, probably both.

The effect of the Wisconsin statutes is to require all persons to obey the subpœna of a court, and their compensation for such obedience is fixed at $1.50 per day, with mileage. In a civil action between private parties those fees must be paid in advance, if demanded. In a criminal case they need not be tendered or paid in advance, though doubtless a contract may in some cases be implied to pay the specified fees for the service. The duty of every witness is to attend as long as commanded, and to testify to all material facts within his knowledge. This is a duty resting on all members of the community as such to aid the courts in the administration of justice and insistence on it by the courts does not constitute such a taking of property as is forbidden by the Constitution.

This was not seriously controverted by the plaintiff's counsel in its application to what they called ordinary witnesses testifying to ordinary facts, but they contended that, when a physician is called on to give expert testimony, his services are of a different character, and can not be demanded without compensation.

The word "expert" in this connection is somewhat loose and uncertain. Much of the testimony of a so-called expert is in no wise different in character from that of any other witness. He may be called on to testify to that which he sees, hears, or otherwise discovers by the use of his senses; but those facts may be such that no one but a trained expert would discover them by such use of his senses. A skilled physician discovers facts by the use of sight, hearing, or feeling which another man might not. But this distinction is one of degree merely, and not of kind. All men differ in their ability to observe accurately and in the certainty of knowledge which they derive from such observation. An illustration of such testimony, not in the legal sense expert, and yet dependent on the peculiar knowledge and abilities of the witness, is presented in Hocking vs. Windsor Spring Co., 131 Wis., 532, where an oculist, not competent under the Wisconsin law to testify as an expert, was allowed to testify to physical injuries which doubtless could not have been seen and discovered or described by a nonprofessional.

There can be no doubt in this field that every man owes a duty to attend and testify to the material facts that he knows notwithstanding the knowledge thereof may be due either to his learning or his expert faculties. Any attempt to draw a line between the exceptionally stupid and non-observant person and others who, by greater alertness, training or skill in observation, may acquire more knowledge, is impracticable and irrational. The educated and intelligent owe the same duty of aid to the courts up to the limit of their ability as does the less competent man--the man whose services are worth $50 per day as well as he whose time is worth but $2.

The more difficult field is entered when the court approaches the question of calling on men of exceptional experience and qualifications to give their opinion as the result either of facts which they observe or from an hypothetical statement of facts. This is the real field of expert evidence. It is there that the expert can testify and the non-expert can not. But here also the expression "expert" is of very broad meaning. It includes the mechanic, whose opinion may be asked on the strength or value of a brick wall or chimney, or the farmer, with reference to quality and value of lands, crops or farm animals, as well as the man of most abstruse research and learning in the fields of chemistry and bacteriology or medicine. So here, again, no line can be drawn on principles between the men or the testimony in favor of a physician over a bricklayer.

It would seem on principle, in analogy to the previous discussion, that, if from the witness' observation or from the hypothetical facts stated to him he has consciously in mind either knowledge or an opinion, such knowledge or existent opinion is a fact as to which he may be required to testify; but, as is often the case, and in the higher branches of expert learning perhaps usually, an amount of study, experimentation, thought, and reflection may be necessary to the formation of an opinion, and the witness may often honestly answer that he has not formed such opinion. The chemist, after submitting a substance to various analyses and reactions, may yet need to study the books or make further experimentation before he can assert the presence or absence of certain elements. The physician, after exhaustive inspection and tests, is still often left in doubt, and does not venture an opinion to his patient until after long study. Such study, reflection, etc., is not the function of the ordinary witness. It is not within the command of the subpœna, and there is no reason to think that the statutes were intended to require it of any witness merely as such. If a party desires that any witness, expert or otherwise, equip himself with knowledge by research or inspection, it may employ him to do so, but such employment will be controlled by the ordinary rules of contract, express or implied.

In some of the earlier text-books and decisions it was asserted that courts could not or would not compel certain professional men to attend and testify on professional subjects for the mere ordinary witness fee, more especially on the ground that the time of such witnesses was so valuable that they ought not to be thus coerced. Most of these seem to result from a custom amongst the English courts to treat physicians and lawyers as exempt from coerced attendance on the same terms as other witnesses, a custom often criticized, but which had some justification in an early statute which provided for the tender to a witness "according to countenance or calling his reasonable charges."

The fallacy of the reason on which these earlier customs were supported has, however, been recognized and their authority repudiated in a great multitude of more recent decisions. The result of these cases is that the expert, be he mechanic, physician, engineer, or chemist, must obey the subpœna of the court, and must testify to such facts as are within his knowledge, whether these facts may have required professional learning, study, or skill to ascertain them or not. If, when placed on the witness stand, he has such knowledge, he must testify to it. They substantially all recognize, however, that the subpœna under statutes like those of Wisconsin does not compel the expert or other witness to equip himself by labor with ability to testify either to an opinion or to any other fact which might be ascertained by special services, and hence that from the mere subpœna and compulsion to testify as a witness results no implied contract on any one to pay the expert anything in excess of the statutory fees, recognizing, however, that, if he does perform work in preparation and qualification to enable him to testify at the request of any person, implied contract for reasonable compensation may arise, or an express contract will be valid.

Applying these principles to the present case, it is very obvious that no statute in Wisconsin has authorized any one to make any contract for such services at the expense of the county. The allegation of the complaint was that all services of that character were performed at the request of the attorneys for the accused, albeit with their assurance that the county would be liable therefor. Liability can not be imposed on counties or other governmental subdivisions of the state except in accordance with statute law, and no statute was referred to conferring any such authority on counsel for one accused of crime. The court is therefore unable to discover any basis on which the county of Waukesha could be held liable for any compensation to this witness other than the statutory fees, if indeed it could be made liable for those.

The right to fees from the public must be found in the statute. Nowhere in the Wisconsin statutes is there any provision for the payment of a defendant's witnesses except in Section 4062 of the Wisconsin Statutes of 1898, which permits witnesses "ordered" for the defendant by the court or judge to be paid their fees out of the county treasury in the same manner that witnesses for the state therein are paid; that is, only on a certificate of the clerk of court (Section 4060) after a prior order by court or judge. This is a necessary prerequisite to the existence of any liability of the county therefor. The complaint in this case failed to allege either any order of court or judge for the appearance and attendance of the plaintiff, and the form of procedure in presenting his claim to the county board at least impliedly negatived the issue of any certificate by the clerk of court. Without such prerequisites, no cause of action, even for the amount of the statutory fee, can be stated. The court therefore concludes that the complaint failed to state any cause of action against the county.

8 Case of Hemorrhagic Renal Infarct. F. R. McCreery, New York.

6. **Diphtheria.**—A summary of the 41 cases reported by Wuttke may be made as follows: In 13 cases there was a typical pseudomembrane. The bacilli were longer than in the non-membranous, averaging 3 microns on the 24-hour cultures; the cases ran a more severe course and were frequently followed by paralyses. Twenty-eight cases never exhibited membrane at any time. The bacilli in these non-membranous cases were smaller than those in the cases with membrane, running from 1 to 3 microns, most of them being about 1.5 microns long. These cases ran a milder course throughout, responded readily and in a characteristic manner to treatment by antitoxin, none developed paralysis. It would seem that in these cases the bacilli belonging to the short variety were not so virulent as the longer forms in the cases with membrane. One case followed a peritonsillar abscess after its spontaneous rupture. Two cases followed scarlet fever, with an interval of perfect health of four and seven weeks, respectively. One case was followed by an abscess due to staphylococci and streptococci, which was treated surgically. Paralytic sequelæ were noted in 5 cases. In three of these there was a myocarditis. Antitoxin in doses of 4,000 units was administered to all patients as early as possible. In 2 advanced cases this dose was repeated twice. Recovery was complete and prompt in all cases. No local treatment was used in any case. Prophylactic doses of 1,000 units each were given to 54 individuals who had been exposed. None of these developed the disease. The only undesirable effect of the serum noted was an urticarial eruption in about 20 per cent. of all cases, but most frequently in those cases in which only 1,000 units had been administered.

14 The Importance of Distinguishing Simple Round Ulcers of the Duodenum from those Ulcers which Involve the Pylorus or are Above it (concluded). E. A. Codman, Boston.

10. **Spina Bifida Occulta.**—Sever reports 11 cases, the deformity occurring in the cervical region in 4 cases, the dorsolumbar region in 1 case and lumbar region in 6 cases. Paralyses were present in 4 cases; dislocation of hip in 2 cases, and scoliosis in 2 cases. Sever says that operation is not indicated in a large number of these cases, especially when not accompanied by pain, anesthesia, hyperesthesia or complete paralysis. In a number of cases, the deformity itself cannot be corrected and one has to devote attention to the complications. Hypertrichosis is not constant, but is more frequent in the low dorsal and lumbar region. Lateral curvature may or may not exist, and if it does, it is to be treated as such. Prognosis for life is good and in the paralytic cases not a great deal can be done except to attempt to correct the deformity.

11. **Cysts of Long Bones.**—Simmons reports three cases of the rarer forms of bone tumors: (1) Bone cyst of the head of the humerus with fracture; (2) bone cyst of neck of femur, with fracture; and (3) bone cyst of shaft of femur, with spontaneous fracture. From a review of the literature and the history and findings in these three cases, Simmons draws the following conclusions:

> 1. The so-called solitary cysts of the long bones are in most cases due to the degeneration of pre-existing tumors, that is, growth and softening of a chondroma arising from a misplaced piece of epiphyseal cartilage. This theory, however, does not account for all the cases.
> 2. The tumors are essentially benign growths and may be cured by a conservative operation.
> 3. They are seen almost exclusively in children and young adults
> 4. In any case of spontaneous fracture or fracture following slight violence, a radiograph should be taken to determine the presence or absence of a bone cyst as a predisposing cause.
> 5. A positive diagnosis is impossible without a radiograph, which should be examined by a man conversant with the appearance of bone tumors.

17. **Determination of Casein.**—The method described by Van Slyke and Bosworth is said to require only apparatus and reagents that are in common use; its operation in the determination of casein in a sample of milk requires only from 12 to 15 minutes; and the results usually come within 0.1 or 0.2 per cent. of the correct amount. With the proper equipment several samples can be run simultaneously with much economy of time. A given amount of milk, diluted with water, is made neutral to phenolphthalein by addition of a solution of sodium hydroxid. The casein is then completely precipitated by addition of standardized acetic acid; the volume of the mixture is made up to 200 c.c. by addition of water and then filtered. Into 100 c.c. of the filtrate a standardized solution of sodium hydroxid is run until neutral to phenolphthalein. From the difference between the amount of acid and the amount of alkali used, a simple calculation enables one to determine the percentage of casein in the milk examined. The method is described at length.

18. **Diagnostic Skin Reactions in Acute Infections.**—Deeming it possible to diagnosticate accurately the species and variety of infecting organism by scarifying a small area of the skin with a definite amount of each of the dead organisms suspected, Hirshberg devised the following method: The skin is scarified with sterile water, a salt solution of physiologic strength, or 50 per cent. glycerin and 1 per cent. phenol in isotonic salt solution. This is used as a control. Usually 5 other vaccinations are made. The types of organisms used depend on the suspected infection. A fairly good reaction shows a slightly reddened area in the neighborhood of 5 mm. in diameter with slightly tense, firm and hard center. A moderately good reaction shows the hyperemic area about 10 mm. persistent and distinctly infiltrated. A very good reaction shows a distinctly edematous site about 25 mm. or more and marked infiltration and hyperemia. On what this reaction depends Hirshberg has not yet determined. So far this method has been used in 22 cases. Known cases were sometimes taken in order to determine the value of the method.

19. **Examination of Gastric Contents and Feces.**—The main part of the apparatus devised by Bassler consists of the well-known form of fermentation tube, the upright limb of which has a 15 c.c. capacity and is graduated in per cents., and the bulb a 30 c.c. capacity. The tube is less than 6 inches in height, so that it will go into a medium-sized incubator, and is constructed so that 25 c.c. sufficiently fills the instrument. Into it is placed a portion of an Ewald test meal; or for the chemical test of feces, 7.5 grams of the soft end of a stool (mushy consistence) or 10 c.c. of a fluid stool (each of which are mixed in 25 c.c. of water). In the bacteriologic examinations, the tube is filled with bouillon or a 2 per cent. dextrose in bouillon and inoculated with about 1 c.c. of the test meal or 3 or 4 drops of the watery suspension of feces. In the case of the chemical test of the feces, the weighed portion of the stool is thoroughly mixed with water in a casserole by means of a common teaspoon and any large sticks of cellulose or vegetable substance present removed. The fermentation tube (a) is then placed in a water-jacketed oven, where it is kept for twenty-four hours at 37 C., when the examinations are made. If at the time of examination more or less feces and incorporated gas are seen at the top of the fluid in the upright tube, No. 3 or 4 shot are placed into the bulb which is then filled with water, and corked so that no air from without is confined. After this the instrument is shaken to allow the shot to break up the floating fecal mass at which the gases from it are liberated; such gas as escapes into the bulb is then passed back again into the upright end, the cork withdrawn, some of the fluid run out, and the observations made as follows:

First the total gas content is observed, after which in the feces tests some of the fluid is extracted and examined for indol and uroresin, and in the nutritive media for aerobic bacteria. The carbon dioxid present is extracted by introducing into the contents 1 or 2 c.c. of saturated solution of sodium hydrate by means of the pipette, and the tube inclined to permit this heavy solution to run up into the upright portion and allowing 15 minutes of time for complete extraction. The rise in the fluid corresponds to the amount of carbon dioxid present. The remaining mixed gases are then tested in the twin bottles, being driven through, when the cock is opened, by means of adjustment and blowing. The reactions are noted in the bottle which contains a very weak solution of neutral litmus (a control in a test tube being used to note the color change), or distilled water into which are put small pieces of phenolphthalein and methyl-orange papers (the first turns red with alkalies and the second turns red with acids). Another bottle contains common lead water to note the presence of sulphuretted hydrogen (turns black); and the hydrogen and marsh gas may be ignited at the outlet, but as both of these burn with an indistinguishable blue flame and neither is important in the clinical way, the authors consider that this may be omitted. With the nutritive media the contents of the closed upright limb is then examined for anaerobic bacteria.

20. **Treatment of Recurrent Hordeolum.**—Brav's line of treatment is the following: During the acute stages hot applications are advised. As soon as the acute stage has somewhat subsided, he applies locally the following mixture:

℞.	gm. or c.c.	
Tincturæ arnicæ	16	℥ss
Tincturæ opii	8	ʒii
Liquoris plumbi subacetatis dil.	8	ʒii
Aquæ destillatæ	90	q. s. ℥iii

M. S.: Apply locally by means of absorbent cotton at bed time.

After the disappearance of the stye for a period of four weeks, the following antiseptic ointment is employed:

℞.	*gm. or c.c.*	
Hydrargyri chloridi corrosivi	008	gr. ⅛
Petrolati albi	8	ʒii

M. S.: Externally.

This should not be merely smeared over the lids, but should be applied with gentle massage every night. Prior to the application of this antiseptic ointment hot compresses should be applied to stimulate the circulation of the margin of the lids. While an ordinary stye does not always require the correction of any errors of refraction it is always an essential procedure in the recurrent type. It is often a contributory factor in the development of styes. Having corrected any error of refraction an antiseptic nasal wash is given. A teaspoonful of boric acid in a glass of water to be snuffed up, twice daily, is a good simple procedure. The constitutional aspect of the case must, of course, be remembered. Brav usually employs compound syrup of hypophosphites with good result. In order to keep the bowels in good condition he incorporates the fluid extract of cascara.

℞.	gm. or c.c.	
Extracti cascaræ fluidi	16	℥ss
Syrupi hypophosphati, comp.	90	q. s. ℥iii

M. S.: A teaspoonful three times a day.

This simple method of treatment has never failed in his hands and even the most protracted cases have yielded to this medication within four weeks' time, provided the intelligent cooperation of the patient can be secured.

21. **Mammary Fibroadenoma.**—Denenholz reports a case of this kind in which both breasts of a young male were involved.

31. **Retroperitoneal Lipoma.**—Henderson reports a case in which a tentative diagnosis of ovarian tumor was made, and exploration advised. The abdomen was opened through a median incision. All the intestines, including the transverse colon, were found down in the pelvis, while the stomach and liver were crowded up against the diaphragm. The mass was seen to be retroperitoneal, presenting largely through the gastrocolic omentum, making a tumor a little larger than a full term pregnancy. Fat lobules showed clearly through the peritoneum, and it could be made out that the tumor had its origin in the left kidney region extending through the mesentery well across into the right side. The posterior layer of the peritoneum was incised, and the tumor seen to be non-encapsulated. It was carefully shelled out, the greater part coming in bulk, but much of it being taken out piecemeal. The kidney was not molested, as it was not densely adherent to the growth. Comparatively little bleeding was encountered, and that was controlled by clamps and afterward by ligation. The posterior layer of the peritoneum was then drawn together, and the median incision closed in the usual manner. No drainage was provided. The tumor weighed 19¾ pounds. Recovery was uneventful, the patient returning to her home in three weeks.

41. **Thyroidectomy in Catatonic Dementia Præcox.**—In three patients operated on by Kanavel seven-eighths of either the right or left lobe of the thyroid was excised without cutting any muscle, except the platysma. The patients all made an immediate and uneventful recovery. The glands were sectioned and studied. In three cases parathyroids were removed by choice to note what effect this might have on the course. Two glands were practically normal, two showed excessive parenchymatous growth; one was a marked colloid growth. Marked hyperemia was present in all of the glands and microscopic hemorrhage was commonly present. So far as could be determined the parathyroids removed did not show any characteristic pathologic change. Kanavel concludes that while one cannot assume any distinct pathologic basis for ascribing dementia præcox to a hyperthyroidism similar to Graves' disease, the pathologic picture cannot definitely exclude a perverted thyroid metabolism as a factor. Partial thyroidectomy is absolutely of no avail in old cases. But when one remembers that Berkley has had five patients apparently completely recover and Kanavel has had two greatly im-

proved, if not cured, by this procedure, and nothing else is known which may offer any hope in this group of psychoses, it seems justifiable to continue investigations in the early cases.

53. **Bactericidal Substances in Fibrin.**—The claim has been made in recent years that fibrin is a carrier of considerable quantities of bactericidal and hemolytic substances, and therefore is an important therapeutic means in the combating of infections, chiefly of a localized inflammatory nature. Bergel claims to have found both antibodies and complement in washed fibrin, and was the first to make practical use of this element of the blood as a therapeutic agent. Coca repeated some of the experiments described by Bergel, and always with the same result, namely, that there is an incomparably greater quantity of the substances under consideration in the serum than in the fibrin of the same specimen of blood. Consequently, the logical conclusion of his study is that dependent on the classes of substances under investigation, it must be considerably more advantageous to use the corresponding serum for the purpose of treatment. However, it becomes apparent that if the injected fibrin does prove to be efficacious in the cases mentioned, it will not be because it carries bactericidal substances.

56. **Indian Form of Relapsing Fever.**—Experiments conducted by Strong seem to show that Bombay spirillum fever is distinct from African tick fever, but that it constitutes a form of relapsing fever very closely related to, if not identical with, the forms of relapsing fever encountered in Europe and the United States. However, it does not yet seem clearly demonstrated that the American and Indian strains are distinct from the European, if not identical.

68. **Islands of Langerhans and Glycosuria.**—MacCallum found that when a portion of the pancreas is separated from the rest and its duct ligated, it undergoes extensive atrophy, a tissue remaining which is apparently composed of enlarged islands of Langerhans and the remnants of pancreatic ducts. If the rest of the pancreas be removed, this atrophied remnant is capable of warding off glycosuria even when considerable amounts of dextrose are ingested. When it is removed also, glycosuria appears at once spontaneously. Whether the glycosuria would persist until the death of the animal remains to be determined, but MacCallum believes that this experiment suggests the possibility that there may be some compensation on the part of other organs, both with regard to glycosuria and the faulty assimilation in so far as it was intended as a demonstration of the specific control of carbo*hydrate metabolism by the islands of Langerhans.*

69. **Tuberculosis of Parathyroids and Tetany.**—During the past year, two patients suffering with tetany as a terminal complication of acute miliary tuberculosis have come to autopsy at the Johns Hopkins Hospital. Both patients were colored women, aged 21 and 26 years respectively. The illness was acute, and in both cases typical symptoms of tetany had been observed during life. At autopsy both showed general miliary tuberculosis. In one of the cases there was a small focus of tuberculosis in one parathyroid gland. The parathyroids were not carefully examined in the first case, but *it is interesting to note that the convulsions immediately sub*sided following the injection of calcium into the arm vein. Winternitz holds that it seems quite possible that in certain cases of tuberculosis there may be a marked disturbance in the calcium metabolism. This might be of sufficient extent alone to bring about a deficit in the calcium of the circulating fluids, and in this way cause an hyperexcitability of the nerve cells. This is at least a tempting hypothesis which would explain tetany in some cases of tuberculosis in which no lesion of the parathyroid is demonstrable. On the other hand, if there is already a deficit of calcium in the circulating fluids of the body, a slight injury to the parathyroids might very readily be of crucial importance and cause sufficient additional disturbance in the calcium metabolism to bring about tetany.

70. Abstracted in The Journal, Aug. 7, 1909, p. 478.

72. **Chloroform Poisoning.**—Whipple and Sperry report the results of experiments which they believe prove beyond doubt that chloroform is a powerful poison, that narcosis with this drug for any considerable length of time invariably causes central necrosis of the liver (in animals), and that this necrosis, if extreme, will cause death. The essential change is an extensive necrosis and fatty degeneration of the liver. There may be numerous ecchymoses and hemorrhages into the peritoneum or upper intestinal tract. The pancreas may show many fat necroses and ecchymoses. The kidney and heart may present a moderate grade of fatty degeneration. Repair is effected by solution of the necrotic liver cells and rapid multiplication of the remaining peripheral cells. Cirrhosis does not follow extensive central necrosis and repair.

73. **Nitrites in Accidents During Anesthesia.**—According to Plant, the administration of nitroglycerin or other nitrites in accidents during anesthesia is not only contrary to the principles of rational therapeutics, but a dangerous procedure as well. Experiments by Plant demonstrated that nitroglycerin only exaggerates the depression of the heart and respiratory

center when it is given during those stages of anesthesia where a stimulant is indicated; for instead of having a beneficial effect in these experiments it prevented the recovery of the animals, even when artificial respiration was performed. The failure of these animals to recover from the anesthetic when nitroglycerin was used, could only have been due to the nitroglycerin itself; for in the last series of experiments in which exactly the same conditions prevailed as to anesthesia, the injection of true cardiac and respiratory stimulants (i. e., strychnin and cocain) was sufficient to bring about the recovery of the animals without any artificial respiration.

74. **Neoplasms of Uterine Adnexa.**—The cases reported by Stout are (1) bilateral fibromata of the ovary; (2) primary myoma of the broad ligament; (3) sarcoma of the ovary; and (4) primary adenocarcinoma of the Fallopian tube.

90 Cerebrospinal Meningitis. J. B. Marvin, Louisville.

88. **Cancer.**—One of Sherrill's patients was a young man, 25 years of age, who had been suffering from symptoms of obstruction. On examination of the rectum, Sherrill found a hard cancerous tumor surrounding the gut about two inches above the anus. The patient's mother, a woman about 47 years of age, who had been having uterine hemorrhages, on examination was found to have an epithelioma of the cervix.

89. **Subperitoneal and Retroperitoneal Fibroid.**—On opening the abdomen half of the tumor was found above and the rest of it wedged into the pelvis. It could not be moved or lifted out of the pelvis; the peritoneum hugged the tumor pretty closely, passing on to the rectum. On the left side, however, was a large pus tube which had been leaking, over which tube was agglutinated the sigmoid and one coil of small gut, but as soon as these were separated the pus began to escape. Frank walled this side off with gauze and then placed a large clamp on the tube on the left side, ligated the tube and ovary on the other side and cut them away; then clamped the round ligament, then deflecting the bladder downward over the front of the tumor, the broad ligament was opened up and the ureter and uterine vessels were exposed. The uterine vessels were isolated and caught with a clamp and then the tumor was cut across. He tied all the vessels, then passed the hand down between the vagina and the deep pelvic portion of the tumor, separating the vagina, then lifting the tumor away from the separated vaginal wall with the right hand; the peritoneum on each side was made taut and split, leaving the tumor unattached and easy to roll out. As soon as it came out the tumor assumed a cylindrical shape. It sprang entirely from the posterior wall of the uterus. Frank never before removed a tumor in this manner, nor has he seen any mention of such a procedure.

111. **Exophthalmic Goiter.**—Guthrie reports three cases of exophthalmic goiter treated successfully with Beebe's serum. The symptoms were typical, so that there was no doubt about the correctness of the diagnosis. The cases were recent ones. A cure was effected in each instance in about three months.

113. **A New Suture.**—McMillen has devised a suture which he believes to be superior to the sutures commonly employed. It is made as follows: First put in the suture the same as the ordinary interrupted suture. Thread the reverse end of suture, insert needle into the skin very close to the edge of the wound, about one-sixteenth of an inch. Pass the needle through the skin only, and on over, and catch the skin on wound side and come out on cuticle side about one-sixteenth inch from edge. The suture is then tied by a reef knot drawn with sufficient force to bring deep structure together. The inner margins of the skin will then be seen to be in exact apposition, and the cut surfaces of the skin will be together when the pressure of the dressing is applied. The knots are at the side of the wound, and their removal will not disturb the line of union. The line of union is not constricted by the suture and the blood and nerve supply is not interfered with. He states that this suture reduces the size of the scar to a minimum.

126. **Chronic Colitis.**—Fulton's paper is a summary of 158 cases of chronic colitis in which the disease was limited to a large bowel. Of the 158 cases, 67 were males and 91 were females. The youngest individual was a boy of 6 and the oldest a woman of 65; 75 per cent. of the patients were from 20 to 50 years of age. The duration of the disease was from 2 months to 20 years. One hundred and forty-two, or 85 per cent., were poorly nourished; ptosis of the stomach was present in 118 cases. The right kidney was palpable in 53, both kidneys in 15, and the left kidney alone in 2 cases. Ninety-two had the "habitus enteropticus;" 154 had chronic constipation. In 131, the constipation was of the spastic variety. Four of the 158 patients had diarrhea, and 7 alternating constipation and diarrhea; 3 stated that their bowel functions were normal.

The symptomatology consisted of constipation, mucus, flatulence and abdominal distress, besides a large number of reflex, nervous, dyspeptic and circulatory disturbances. The treatment was based on the principle that in the large majority of cases chronic colitis is a superficial catarrh of the large bowel which accompanies chronic constipation. Contrary to usual custom no treatment was directed primarily to the nervous system. Endeavor was made to restore, when indicated, the abdominal pelvic organs to their normal anatomic relations. Properly-fitting abdominal supporters or corsets were therefore invariably prescribed when marked ptosis of the stomach or colon was present, and for displacements of the uterus operations for their correction were advised. In two cases colonic adhesions were no doubt the cause of the constipation and its resulting colitis. One of these patients was permanently cured by surgical treatment. The other presents evidence of reformation of adhesions since the operation, two months ago. Twenty-eight of the 158 patients have been lost sight of; of the remaining 130, 18, or 14 per cent., received no benefit, or soon relapsed after the cessation of active treatment; 36, or 28 per cent., were greatly benefited, by which is meant freedom from symptoms, except an occasional temporary return of constipation; 76, or 58 per cent., have remained well.

138. **Reverse Peristalsis.**—Brown did a posterior drainage operation with the Murphy button to relieve the symptoms dependent on carcinoma of the pylorus in a man of 65. The stomach was found to be about normal in size. The immediate convalescence was uneventful—patient was home in two weeks and was eating and enjoying solid food in the third week. Free easy bowel movements occurred daily. One month after the operation, having been outdoors and very comfortable all the morning, the patient had a light luncheon, immediately followed by abdominal pain, severe enough to send him to bed. He felt nauseated and vomited a small amount of greenish-yellow fluid. Shortly after he had a large, free evacuation. During the afternoon the patient was not especially uncomfortable, though he had some pain. Toward evening the nurse noted that the abdomen was a trifle distended and hard. She gave one and one-half quarts of a saline solution—three large teaspoonfuls of salt to a quart of water—which failed to give relief. Immediately the abdomen progressively increased in size. Becoming alarmed, the nurse gave another quart and a half of saline enema. This, too, failed to relieve, and the abdomen attained still greater dimensions. The patient vomited volumes of fluid of a very salty taste and containing fecal matter. Examination revealed a patient practically in collapse. Eserin 1/50 and atropin 1/60 hypodermically were given at once. The patient was turned on his left side. No more vomiting occurred, the abdomen rapidly fell to its normal proportions and the pulse dropped to 90. By midnight the patient was asleep and had a fairly easy night. The next afternoon, by enema, there was a large, loose movement in which the button came away.

139. **Mercury in Tuberculosis.**—The results obtained by Mosely in 33 cases are as follows: Marked improvement, 5 (15.15 per cent.); slight improvement, 11 (33.33 per cent.); stationary, 8 (24.24 per cent.); failed, 4 (12.12 per cent.); died, 5 (15.15 per cent.).

149 *Arthrodesis for Flail-Foot. A. R. Shands, Washington.
150 Specimens of Urinary Calculi. H. A. Fowler, Washington.

146. **Insanity.**—In acute insanity the treatment employed by Hunt resolves itself into rest in bed, overfeeding, wet pack, fresh air and the occasional use of drugs, as may be indicated. The patient should be put to bed at once. Remove all sharp instruments, drugs, etc., have the windows so arranged that they may not be opened over six inches. The bed treatment impresses the patient with the fact that he is ill, and by further impressing the fact that the illness is curable, and by not occupying the patient's mind with games, odd jobs, etc., but by treating the disease as an ordinary illness, we obtain both physical and mental rest, and the result is a more frequent and speedy recovery. If motor excitement be present, it may require the temporary use of drugs, but it is much better for the patient to resort at once, if possible, to hydrotherapy. The warm bath produces diaphoresis, influences the circulation, lowers the blood pressure, causes the elimination of morbid products, renders the surface of the body less sensitive and produces a sedative action. The cold bath should be used only in cases that respond to the severe shock produced by the application of cold water to a large surface of the body, and it should be followed by energetic rubbing. It increases the nervous energy, stimulates the functions of the body and raises the blood pressure. The spray, either warm or cold, should follow the bath in suitable cases, for about five minutes. It is produced by a nozzle attached to a rubber tube which is connected with the spigot. The wet pack is very useful in excited patients, as well as in insomnia. It may be used either hot or cold, as the condition of the patient warrants, and may be continued for from twenty minutes to several hours. The wet pack also proves a good temporary restraint for excited patients. Insomnia is almost a constant feature of the acute forms of insanity. Drugs should be used only when indicated. Massage and gentle faradism are useful aids to nutrition. Overfeeding is necessary to restore the great waste of tissue going on in the system. As autointoxication is a frequent factor in the etiology of insanity, the alimentary canal should receive prompt and careful attention, the result at times of such attention being most gratifying.

149. **Arthrodesis for Flail-Foot.**—Shands' patient was a little girl, the victim of acute anterior poliomyelitis, both feet having been paralyzed; one foot remained completely useless and was a source of annoyance on account of its extreme flexibility—such as to make the term dangle-foot or flail-foot applicable. The operation of arthrodesis was done, after the method of Whitney. It consisted simply in opening the joint and denuding the articular surfaces—in this case those of the astragalus and the bones of the leg; the result was a beneficent ankylosis. The improvement in the girl's locomotion was very marked.

156. **The Cancer Problem.**—It is generally accepted that cancer develops especially in tissues exposed to long-continued irritation, and in scars, chronic ulcers, etc., of long standing. This so-called "precancerous" condition in the stomach is furnished by chronic gastric ulcer, and yet in 1,112 operations on the stomach and duodenum in one clinic there was but one instance of duodenal ulcer becoming carcinomatous. It has been very interesting to Westbrook to note, often, how gastric cancer will extend along the stomach to the pyloric ring, and then stop suddenly short in its progress in that direction, not at all involving the duodenum. The most striking difference in the involvement of the duodenum by cancer as compared with the stomach has received as yet no attention, beyond the statement of the fact, and an adequate explanation of this difference would be going a long way toward solving the cancer problem. Either it is a mistake that ulcer often forms a precancerous stage in the stomach, or there is lacking in the duodenum the essential cause which gives origin to cancer. There is nothing in the tissue formation of the stomach and of the duodenum to explain the great difference, and no one has shown that misplaced histologic cell-elements which might give rise to new growths are vastly more common in the stomach than in the duodenum. Westbrook asks whether this can be explained on the theory that cancer is due to a parasitic cause. It would seem that this would form a reasonable explanation, and that the intestinal secretions are the inhibiting cause which prevents the frequent occurrence of cancer in the upper intestinal tract.

163. **Myasthenia Gravis.**—Spear reports a typical case of myasthenia gravis, pursuing a characteristic course, beginning with transient weakness of the ocular muscles and muscles of mastication, later involving all the voluntary muscles, the respiratory and cardiac muscles, terminating in about four years with cardiac asthenia. There was also present a mediastinal tumor.

3. **Nerve Anastomosis.**—The types of paralyses for which Tubby has performed anastomosis are (1) traumatic and (2) infantile paralysis. The total number of patients operated on is eight. These have been watched for a period of not less than 3 years since the operation. Of the 8 cases quoted, 2 were of traumatic origin, of which one patient recovered after complete severance of the nerve, and the other is showing steady progress toward recovery. Of the cases due to anterior poliomyelitis, 6 in number, in 4 there is distinct evidence of a more partial recovery of the muscles, but in 1 of these cases improvement has ceased for a year. In 2 others no clinical signs of regeneration are apparent, even after 4 years. In 1 of the latter cases operative exploration showed, however, that the external popliteal nerve was being regenerated centrifugally.

5. **Delayed Chloroform Poisoning.**—Weir's case presents several points of interest. The abdomen was opened and drained for an abscess which extended down into the pelvis. The anesthetic administered was chloroform, which was taken exceedingly well, the time occupied being about three-quarters of an hour. After the operation, the patient was restless and complained of a good deal of thirst, but vomited once only and that was twelve hours afterward. Saline solution was administered by rectum on account of the thirst. For forty-eight hours the patient seemed well, except for restlessness; the temperature was normal and the pulse good. On the following day, however, the restlessness had become a maniacal delirium, the patient screamed, threw the clothes about, tore off his dressings, and had to be placed under mechanical restraint. There was almost entire absence of vomiting. The urine showed diacetic acid when tested with liquor ferri perchloridi, and although the quantity of urine was not measured, it was judged by the nurse to be about normal. Rectal injections and sodium bicarbonate were continued, and a solution of glucose, half an ounce to half a pint of milk was administered by the nasal tube, and a 10 per cent. solution by the rectum. This was given once every four hours, and, in addition, a good supply of carbohydrate food. For the next twenty hours the patient went from bad to worse, the face became a rich plum color, the coma deepened, frothy saliva oozed from the mouth, and the prognosis seemed absolutely hopeless. Typical Cheyne-Stokes respiration was present, and the sweating was profuse. The pulse, however, remained good, and was never above 108 a minute. The patient retained everything given by the nasal tube and by rectum. After remaining in this desperate-looking condition for a few hours, he began to show a little improvement, the first sign being an attempt to move his head. Within six hours, in fact, the intellect was quite clear and the patient expressed a wish for some food. Recovery was perfect.

59. **Retropharyngeal Abscess.**—Rösling epitomizes 17 cases in which operation was by the Chiene technic, and extols its advantages. Recovery was prompt and complete in all but 3 cases in which the patients succumbed to the progress of advanced tuberculosis. He compares the outcome with this technic in the hands of various surgeons with the outcome when the Burkhardt or other technics were followed, the results sustaining his assertions, he declares, *in regard to the superiority of the Chiene method.*

60. **Spinal Anesthesia in 600 Cases.**—Meissner remarks that the recent improvements in the methods of local anesthesia will restrict the field of spinal anesthesia more and more as, even in the hands of experts, it cannot be regarded as free from danger, although it has proved useful when strictly indicated. In 15 of the 600 cases in which spinal anesthesia has been used at von Bruns' clinic at Tübingen, the spine was deformed, the ligaments ossified or the patient was obese to such an extent that it proved impossible to introduce the needle. By using minute amounts of the anesthetic and refraining from raising the pelvis, the anesthesia proved sufficient for operations below the umbilicus, free from threatening mishaps while the by-effects and after-effects were much reduced.

66. **Study of the Vital Processes by Incorporation of a Stain.**—Goldmann injected white mice subcutaneously with 1 c.c. of a 1 per cent. solution of pyrrhol blue and obtained most interesting findings with this "vital staining" which did not seem to injure the health of the animals in the least, although the illustrations show that they had "the blues" to an unprecedented extent. The stain was attracted to different tissues in different ways, and revealed vital processes of internal secretion as well as external, throwing light on many hitherto obscure points, especially in the gravid animals. One of the facts learned was the presence of a certain granulated cell in the connective-tissue cell wherever important metabolic processes were taking place. This cell shares with the stellate liver cells and some others the property of taking up and [illegible] substances dissolved in the blood and holding them a long time.

80 Masked Chlorosis. (Ueber "larvierte" Chlorose.) F. Seiler.

76. **Simple, Practicable Tests of Stomach Functioning.**—Nadler extols the simplicity, reliability and diagnostic importance of Sahli's desmoid test of stomach functioning; this is merely the ingestion of a pill of methylene blue around which is drawn tight a tiny square of thin rubber tissue tied with catgut. As the catgut dissolves in the stomach, the rubber springs open and throws out the pill. A positive reaction indicates that the gastric juice is normal or with an excess of acid or pepsin or both. A negative reaction indicates little or no acid or pepsin or else excessive motility. He gives the patient the blue pill tied up in its bag, and also four half-ounce bottles, the corks marked, respectively, I, II, III, IV. The pill is taken with the noon meal and the urine, voided at three-hour intervals thereafter, is poured in turn into the first three bottles, and the urine voided next morning in the fourth. After this the patient eats a Boas-Ewald test breakfast at home, and then with the four bottles he returns to the doctor's office. If the first bottle shows a positive reaction, the gastric juice is normal or hyperacid; the latter condition is diagnosed by the subsidence of disturbances on administration of an alkali. If the reaction is positive only in the second or third bottles, the acidity is not excessive and an alkali will not do so good service as hydrochloric acid or pepsin. In case of a negative reaction he siphons out the stomach content if the patient consents; if not, he gives hydrochloric acid and a pill of iodoform. A positive reaction in three or six hours indicates merely lack of hydrochloric acid. If the reaction is still negative, he gives pepsin with the hydrochloric acid and a methylene blue pill. The urine is always green after this, unless there is excessive motility, and if the gastric disturbances have then subsided the assumption is that the trouble is merely a lack of pepsin or excessive motility. If the gastric disturbances persist, he omits the hydrochloric acid; if there is merely a lack of pepsin, the urine next day will give the iodin reaction. If the disturbances still continue, notwithstanding the ingestion of hydrochloric acid and pepsin, the trouble may be due to hypermotility, and the salol test will decide the matter, especially with Huber's modification. With this technic the patients can see for themselves the secretory anomalies and therapeutic results, and the whole procedure has a tranquilizing effect in nervous gastric disturbances.

77. **Simplified Method of Treating Asphyxia in New-Born Infants.**—Volland had just delivered a woman after difficult labor and the child was in livid asphyxia. There was no one to assist him, and he had to act quickly and alone. Without attempting to cut the cord he set the infant up against the inside of the mother's thigh and took hold of it as for Schultze swinging, but he did not lift the child more than just enough to let it hang by its whole weight from his hands and then set it down again, pressing with his thumbs, the mother's thigh meanwhile offering the counter support for the pressure, which simulated natural expiration. He repeated this lifting rhythmically and soon heard the child's cry. He

August 15, XIII, No. 16, pp. 541-576

42 *Pathogenesis of Rachitis. P. Hutinel.
43 *Defective and Perverted Thyroid Functioning in Children. L. Concetti.

42. Pathogenesis of Rachitis.—Hutinel reports research on the bone marrow, bones and cartilage, the conclusions being that the disturbances in rachitis are due to an evolutionary dystrophy affecting the least resistant tissues. During the first three or four months of life all the tissues suffer in case of defective assimilation. But, as the child grows, certain organs acquire greater resistance, while others feel more the influence of the nutritional derangement. These dystrophies are particularly important during periods of intense nutritional activity, that is, during the first two years and in adolescence.

43. Defective and Perverted Thyroid Functioning in Infants.—Concetti ascribes to thyroid insufficiency many of the phenomena noted in young infants, such as a tendency to obesity, to transient edema, cold feet and hands, scanty and brittle hair, vasomotor disturbances, vomiting, somnolency and slight resistance to infections. With artificial feeding, these signs become more pronounced, with eczema, urticaria, tardy dentition, etc. It seems evident that nurslings receive in mother's milk some of the products of the mother's thyroid functioning. The physiologic hypothyroidism of the new-born may assume pathologic proportions; any derangement in thyroid functioning on the part of the mother or wet-nurse may lead to severe symptoms of hypothyroidism in the infant. In several instances in his experience infants became myxedematous when the mothers had goiter. In other cases, the healthy infants of healthy parents became myxedematous when they had a wet-nurse with goiter. All these children were cured with thyroid treatment and change of nurse. Experimental research with goats has confirmed, he asserts, the fact of transmission of thyroid secretion by the placenta and in the milk. He is convinced that in many cases the symptoms of thyroid insufficiency in infants have escaped detection or have been attributed to other causes or grouped in other syndromes. There is a promising field for study, he says, in this infantile disthyroidism and the prompt change for the better under thyroid treatment. Typical, complete forms are rare, but the *formes frustes* are encountered on every hand and have been hitherto classed as "lymphatism," "neuroarthritism," atrophy, rachitis, etc. They all show notable improvement and sometimes a rapid cure under correct thyroid treatment, as he has witnessed in many cases. His pupils are now examining infants in crèches, asylums, schools and dispensaries for signs suspicious of defective thyroid functioning, and are instituting thyroid treatment when possible. With the Wassermann test an excess or lack of thyroid secretion can be determined in animals, but the findings are less decisive in the clinic. In some cases the infants seem to be suffering from excessive thyroid functioning, or the deficiency and excess may alternate. The thyroid treatment should be given with caution. He does not give the details of his dosage, but says that he makes a point of treating the nursing mother also.

44. Syphilitic Phlebitis.—Achard's patient, a waiter 20 years old, presented swelling and pain in the left knee simulating phlegmasia, of abrupt onset, but explained by a history of possible syphilitic infection nearly three months before. There were also evidences of roseola and of secondary syphilitic nephritis, with pronounced albuminuria and edema. Under mercurial treatment the phlebitis and the edema subsided completely, but some albuminuria still persisted when the patient left the hospital about the seventh week.

53. The Guaiac Blood Test and Helminthiasis.—Guiart found the Weber reaction positive in thirteen cases in which the eggs of the trichocephalus were found in the stools, and eggs were never found without this positive reaction occurring sooner or later. The patients were on a diet that excluded all source of error from this cause, so that the conclusion seems inevitable that the trichocephalus induces hemorrhage in the intestines, the presence of occult blood being revealed by this sensitive test. This is of considerable practical importance, as the symptomatic value of the test thus depends on whether the patient is free from the trichocephalus or not. The findings are reliable only when the stool gives negative microscopic findings in regard to this parasite. This test for occult blood is frequently accepted as decisive for cancer of the stomach or intestine, but its differential value is annulled if the eggs of the trichocephalus are found in the stools, and statistics show, he says, that this parasite occurs in about 50 per cent. of the population. He has not found the reaction so constantly in case of presence of ascarides. The Weber test should never be accepted as decisive in case of positive findings unless the stools are examined under the microscope at the same time.

15. Chronic Ulceration of Rectum.—Power reports 9 cases—3 of ulcerative colitis, examples of the condition known as sporadic ulcerative colitis, which is an infective inflammation attacking all parts of the large intestine. It is not identical with dysentery either of the bacillary or amebic type, nor is it quite the same disease as asylum dysentery. There was no cause localizing the inflammation to the rectum in the first and third cases, except, perhaps, the changes occurring in connection with recent parturition. In the second case, the rectum had already been the seat of chronic inflammation, as was shown by the fistulas, and the patient was also suffering from Bright's disease. There were 3 cases of ulcerative colitis occurring in patients who had acquired syphilis. There was one case of chronic ulceration occurring after labor, one case each of anorectal syphiloma, gummatous ulceration, and malignant ulceration of the rectum. Power classifies chronic ulceration of the rectum as follows:

- Chronic ulceration of rectum.
  - Ulcerative colitis
    - *Dysenteric.*
      - Sporadic.
      - Epidemic.
    - "Syphilitic."
    - Tuberculous.
    - Secondary to pelvic cellulitis.
  - Syphilitic.
    - Gummatous.
    - Anorectal syphiloma.
  - Tuberculous.
  - Carcinomatous.

Considerable stress is laid on the part played by infective colitis in producing chronic inflammation of the rectum.

18. Treatment of Fractures.—Pringle favors the extension method in the treatment of fractures of long bone. In his experience the results obtained surpass those by any other method of treatment, operative or non-operative.

33 Heart Block in Acute Rheumatism. J. M. Gill.

30. Anesthetics.—Aspinall presents a most admirable review of the history of anesthesia and discusses tersely, but well, the use and indications for the anesthetics now in use. In closing he emphasizes the following points: 1. Every breath taken by the patient should be felt or heard by the anesthetist. 2. The color should be continually observed and an explanation sought for any change in it. 3. The pulse should be felt regularly. 4. If in doubt as to the depth of anesthesia present, temporarily without the anesthetic. 5. Never attempt to hurry the administration, and do everything quietly, so as not to attract the surgeon's attention and cause anxiety on his part. 6. Have everything ready in case of emergency. 7. Do not be impatient during the induction of anesthesia. 8. Watch the patient and not the operation.

31. Heterophoria as Cause of Intractable Headache.—A cautious central tenotomy of the right superior rectus was performed by Smith in this case. The day after the operation, for the first time for twelve months, the patient awoke free from headache. But it recurred next day and remained. A month later she had only one degree of hyperphoria, instead of two degrees. As the pain persisted, Smith did a small central tenotomy of the left inferior rectus. This, from the day after the operation till the present time, completely removed the headache, but gave rise to constant diplopia, which she had never been conscious of before, and an obvious vertical squint. To shut out the persistent second image, she kept her left eye generally closed (*previously, closing one eye* did not relieve the headache at all), and she became a bright cheerful woman, doing her housework and resuming her sewing. Subsequently, Smith remedied the vertical squint by a carefully performed advancement of the left inferior rectus, which, fortunately, just hit the happy medium and resulted in orthophoria, binocular single vision, and happiness.

34 Congenital Heart Affections, Especially in Relation to Diagnosis. G. Carpenter.
35 *Treatment of Advanced Cases of Acute Diaphysitis. H. M. W. Gray.
36 *Acute Meningitis in Children. F. Tresilian.

35. Treatment of Acute Diaphysitis.—The case reported by Gray was a typical acute suppurative diaphysitis or osteomyelitis of the upper half of the shaft of the left tibia. The upper epiphysis and neighboring knee-joint were, so far as could be ascertained, free from disease. An incision, slightly internal to the crest of the tibia, was made from the upper limit to three-fourths of an inch below the lower limit of denudation of periosteum, down to the bone in its whole extent. The subperiosteal cavity was washed out, first with peroxid of hydrogen (10 per cent.) and then with saline solution. The periosteum, corresponding in extent with the lower three-fourth of an inch of the incision, which was adherent to bone and healthy, was elevated off the bone, which was then chiselled across at the lower end of the incision. The upper half of the tibia was then easily lifted out of its periosteal bed, as it was only very loosely adherent to the epiphyseal cartilage. The cavity thus made was carefully washed out as before, dried, and packed lightly with sterile gauze wrung out of peroxid of hydrogen (3 per cent.). The opening of the medullary cavity of the remaining part of the tibia was previously smeared over with Beck's bismuth paste, so as to prevent any possibly infective material from penetrating to the healthy medullary cavity of the lower part of the bone. The limb was then enveloped in sterile dressings and a moulded splint applied (made of plaster-of-Paris bandages soaked in biniodid of mercury, 1 in 2,000 solution).

The temperature fell to normal in a few hours. Three days later the child was anesthetized again and the gauze removed. The cavity was found to be clean and dry, free from pus. The catgut sutures were tied. Bismuth paste which oozed out between the stitches was lightly wiped away and the skin was carefully sutured with fine catgut. Dressings were applied and the limb placed again in the plaster splint. Small sinuses formed, one at the upper and one at the lower end of the wound. Through the upper sinus the greater part of the bismuth paste was gradually pushed out—as the periosteal cavity became filled with "granulation tissue" and bone. The discharge was a thin, honey-like fluid. At no time was there an ordinary purulent discharge. The lower sinus was found to be due to the presence of a thin flake of necrosed bone, which separated and was extruded during the sixth month. At the end of a month the patient was able to walk freely without pain. Thirteen months after operation she had perfect use of the limb, had no discomfort of any kind, and on examination, apart from the scar, one could make out scarcely any abnormality of the bone. On careful measurement from the upper margin of the internal tuberosity to the tip of the internal malleolus it was found that the affected tibia is one-fourth of an inch shorter than the other.

36. Acute Meningitis.—Tresilian reports four cases: The first case was one of tuberculous meningitis, which began in a hemiplegic form. The second was an ordinary case of posterior basic meningitis in an infant, which left behind it the very unusual sequel of complete deafness only. The next case was a typical and severe one of acute cerebrospinal meningitis. The fourth was a case of posterior basic meningitis.

August 15, XIII, No. 16, pp. 541-576

42 *Pathogenesis of Rachitis. P. Hutinel.
43 *Defective and Perverted Thyroid Functioning in Children. L. Concetti.

42. Pathogenesis of Rachitis.—Hutinel reports research on the bone marrow, bones and cartilage, the conclusions being that the disturbances in rachitis are due to an evolutionary dystrophy affecting the least resistant tissues. During the first three or four months of life all the tissues suffer in case of defective assimilation. But, as the child grows, certain organs acquire greater resistance, while others feel more the influence of the nutritional derangement. These dystrophies are particularly important during periods of intense nutritional activity, that is, during the first two years and in adolescence.

43. Defective and Perverted Thyroid Functioning in Infants.—Concetti ascribes to thyroid insufficiency many of the phenomena noted in young infants, such as a tendency to obesity, to transient edema, cold feet and hands, scanty and brittle hair, vasomotor disturbances, vomiting, somnolency and slight resistance to infections. With artificial feeding, these signs become more pronounced, with eczema, urticaria, tardy dentition, etc. It seems evident that nurslings receive in mother's milk some of the products of the mother's thyroid functioning. The physiologic hypothyroidism of the new-born may assume pathologic proportions; any derangement in thyroid functioning on the part of the mother or wet-nurse may lead to severe symptoms of hypothyroidism in the infant. In several instances in his experience infants became myxedematous when the mothers had goiter. In other cases, the healthy infants of healthy parents became myxedematous when they had a wet-nurse with goiter. All these children were cured with thyroid treatment and change of nurse. Experimental research with goats has confirmed, he asserts, the fact of transmission of thyroid secretion by the placenta and in the milk. He is convinced that in many cases the symptoms of thyroid insufficiency in infants have escaped detection or have been attributed to other causes or grouped in other syndromes. There is a promising field for study, he says, in this infantile disthyroidism and the prompt change for the better under thyroid treatment. Typical, complete forms are rare, but the *formes frustes* are encountered on every hand and have been hitherto classed as "lymphatism," "neuroarthritism," atrophy, rachitis, etc. They all show notable improvement and sometimes a rapid cure under correct thyroid treatment, as he has witnessed in many cases. His pupils are now examining infants in crèches, asylums, schools and dispensaries for signs suspicious of defective thyroid functioning, and are instituting thyroid treatment when possible. With the Wassermann test an excess or lack of thyroid secretion can be determined in animals, but the findings are less decisive in the clinic. In some cases the infants seem to be suffering from excessive thyroid functioning, or the deficiency and excess may alternate. The thyroid treatment should be given with caution. He does not give the details of his dosage, but says that he makes a point of treating the nursing mother also.

44 *Syphilitic Phlebitis. C. Achard and R. Demanche.
45 The Blood in Lead Colic. (Des altérations des globules rouges au cours de la colique de plomb.) N. Fiessinger and A. Peigney.

44. Syphilitic Phlebitis.—Achard's patient, a waiter 20 years old, presented swelling and pain in the left knee simulating phlegmasia, of abrupt onset, but explained by a history of possible syphilitic infection nearly three months before. There were also evidences of roseola and of secondary syphilitic nephritis, with pronounced albuminuria and edema. Under mercurial treatment the phlebitis and the edema subsided completely, but some albuminuria still persisted when the patient left the hospital about the seventh week.

53 *Guaiac Test for Blood in Helminthiasis. (Réaction de Weber et trichocéphale.) J. Guiart and C. Garin.

53. The Guaiac Blood Test and Helminthiasis.—Guiart found the Weber reaction positive in thirteen cases in which the eggs of the trichocephalus were found in the stools, and eggs were never found without this positive reaction occurring sooner or later. The patients were on a diet that excluded all source of error from this cause, so that the conclusion seems inevitable that the trichocephalus induces hemorrhage in the intestines, the presence of occult blood being revealed by this sensitive test. This is of considerable practical importance, as the symptomatic value of the test thus depends on whether the patient is free from the trichocephalus or not. The findings are reliable only when the stool gives negative microscopic findings in regard to this parasite. This test for occult blood is frequently accepted as decisive for cancer of the stomach or intestine, but its differential value is annulled if the eggs of the trichocephalus are found in the stools, and statistics show, he says, that this parasite occurs in about 50 per cent. of the population. He has not found the reaction so constantly in case of presence of ascarides. The Weber test should never be accepted as decisive in case of positive findings unless the stools are examined under the microscope at the same time.

65 Origin of Congenital Dislocation of Hip Joint. (Zur Lehre von der Entstehung der angeborenen Hüftverrenkung.) P. Graf.
66 *External and Internal Secretion Viewed by the Light of Diffuse Incorporated Stain. (Die äussere und innere Sekretion des gesunden und kranken Organismus im Lichte der "vitalen Färbung.") E. E. Goldmann.
67 Nail Extension in Treatment of Fractures. (Ueber Nagelextension.) M. Kirschner.

59. **Retropharyngeal Abscess.**—Rösling epitomizes 17 cases in which operation was by the Chiene technic, and extols its advantages. Recovery was prompt and complete in all but 3 cases in which the patients succumbed to the progress of advanced tuberculosis. He compares the outcome with this technic in the hands of various surgeons with the outcome when the Burkhardt or other technics were followed, the results sustaining his assertions, he declares, in regard to the superiority of the Chiene method.

60. **Spinal Anesthesia in 600 Cases.**—Meissner remarks that the recent improvements in the methods of local anesthesia will restrict the field of spinal anesthesia more and more as, even in the hands of experts, it cannot be regarded as free from danger, although it has proved useful when strictly indicated. In 15 of the 600 cases in which spinal anesthesia has been used at von Bruns' clinic at Tübingen, the spine was deformed, the ligaments ossified or the patient was obese to such an extent that it proved impossible to introduce the needle. By using minute amounts of the anesthetic and refraining from raising the pelvis, the anesthesia proved sufficient for operations below the umbilicus, free from threatening mishaps while the by-effects and after-effects were much reduced.

66. **Study of the Vital Processes by Incorporation of a Stain.**—Goldmann injected white mice subcutaneously with 1 c.c. of a 1 per cent. solution of pyrrhol blue and obtained most interesting findings with this "vital staining" which did not seem to injure the health of the animals in the least, although the illustrations show that they had "the blues" to an unprecedented extent. The stain was attracted to different tissues in different ways, and revealed vital processes of internal secretion, as well as external, throwing light on many hitherto obscure points, especially in the gravid animals. One of the facts learned was the presence of a certain granulated cell in the connective-tissue cell wherever important metabolic processes were taking place. This cell shares with the stellate liver cells and some others the property of taking up and binding substances dissolved in the blood and holding them a long time.

75 Improved Technic for Wassermann Reaction. J. A. Finkelstein.

73. **Threatening Collapse After Injection of Diphtheria Antitoxin.**—A young physician describes the collapse in his own person. It occurred in less than half an hour after a prophylactic injection of 1,000 units of antitoxin. The threatening symptoms lasted nearly three hours and then gradually subsided so that he had quite recovered by the next day. He had noticed from childhood that the smell of horses produced discomfort and symptoms suggesting hay fever; they came on when he went into a stable or was driving. Cows and other domestic animals did not have this effect, and he never had hay fever or asthma. It seems evident that the collapse was due to a special hypersusceptibility to horse serum, and this view is confirmed by the fact that a kind of immunity persisted for three months afterward and then gradually subsided.

80 Masked Chlorosis. (Ueber "larvierte" Chlorose.) F. Seiler.

76. **Simple, Practicable Tests of Stomach Functioning.**—Nadler extols the simplicity, reliability and diagnostic importance of Sahli's desmoid test of stomach functioning; this is merely the ingestion of a pill of methylene blue around which is drawn tight a tiny square of thin rubber tissue tied with catgut. As the catgut dissolves in the stomach, the rubber springs open and throws out the pill. A positive reaction indicates that the gastric juice is normal or with an excess of acid or pepsin or both. A negative reaction indicates little or no acid or pepsin or else excessive motility. He gives the patient the blue pill tied up in its bag, and also four half-ounce bottles, the corks marked, respectively, I, II, III, IV. The pill is taken with the noon meal and the urine, voided at three-hour intervals thereafter, is poured in turn into the first three bottles, and the urine voided next morning in the fourth. After this the patient eats a Boas-Ewald test breakfast at home, and then with the four bottles he returns to the doctor's office. If the first bottle shows a positive reaction, the gastric juice is normal or hyperacid; the latter condition is diagnosed by the subsidence of disturbances on administration of an alkali. If the reaction is positive only in the second or third bottles, the acidity is not excessive and an alkali will not do so good service as hydrochloric acid or pepsin. In case of a negative reaction he siphons out the stomach content if the patient consents; if not, he gives hydrochloric acid and a pill of iodoform. A positive reaction in three or six hours indicates merely lack of hydrochloric acid. If the reaction is still negative, he gives pepsin with the hydrochloric acid and a methylene blue pill. The urine is always green after this, unless there is excessive motility, and if the gastric disturbances have then subsided the assumption is that the trouble is merely a lack of pepsin or excessive motility. If the gastric disturbances persist, he omits the hydrochloric acid; if there is merely a lack of pepsin, the urine next day will give the iodin reaction. If the disturbances still continue, notwithstanding the ingestion of hydrochloric acid and pepsin, the trouble may be due to hypermotility, and the salol test will decide the matter, especially with Huber's modification. With this technic the patients can see for themselves the secretory anomalies and therapeutic results, and the whole procedure has a tranquilizing effect in nervous gastric disturbances.

77. **Simplified Method of Treating Asphyxia in New-Born Infants.**—Volland had just delivered a woman after difficult labor and the child was in livid asphyxia. There was no one to assist him, and he had to act quickly and alone. Without attempting to cut the cord he set the infant up against the inside of the mother's thigh and took hold of it as for Schultze swinging, but he did not lift the child more than just enough to let it hang by its whole weight from his hands and then set it down again, pressing with his thumbs, the mother's thigh meanwhile offering the counter support for the pressure, which simulated natural expiration. He repeated this lifting and pressure rhythmically and soon heard the child's cry. He then attended to the umbilical cord. The advantages of this procedure are that no precious time is lost, the child is not chilled, while the expiration rhythm can be made to correspond with the natural tempo and the maneuver is free from the dangers of Schultze swinging and other technics, while it is much less fatiguing for the obstetrician.

78. **Endemic Goiter.**—Kolle states that 6 or 7 per cent. of the recruits in the Swiss army each year present a goiter, and that the proportion of cretins and goitrous individuals is about as high in the Alpine regions surrounding Switzerland

proper. In certain towns in Switzerland from 80 to 90 per cent. of the children were found goitrous in 1908, the same proportion that was recorded in 1886. He adds that the thyroid is always found unusually large in the cadavers in Berne and other foci of endemic goiter, and the same is observed in domestic animals, especially in dogs. The evidence seems to incriminate the water, he reiterates, either as the bearer of some living virus or some chemical substance affecting the thyroid gland injuriously. In two endemic foci the tendency to goiter seemed to disappear when a new source for the water supply was utilized. He urges the medical profession to pay special attention to the influence in this line of boiling the water. Laborious research to isolate some special substance from the goitrous thyroid or the stools or to immunize against goiter has proved disappointing to date, as also all experiments for direct transmission of goiter to animals, but this research has cleared the way for future work, and he urges all the members of the profession in Switzerland to preach the necessity for individual prophylaxis by boiling or filtering the drinking water and for public works to provide an unobjectionable water supply.

81. **Thrombosis in the Mesenteric Vessels.**—Neumann has encountered five cases of a syndrome diagnosed as due to embolism or thrombosis of the mesenteric arteries or veins. Only one of his patients presented the entire quintette of signs that point to this affection, namely, a source for the embolism; abdominal colic; functional disturbance in the digestive tract; tympanites and palpation of bunches between the sheets of the mesentery which can be only engorged blood-vessels. A source for the embolism or a predisposition to thrombosis was discovered in 58 per cent. of 96 cases on record; colic was observed in 84 per cent.; functional intestinal disturbances in 86 per cent., while the complete picture of mechanical ileus was observed in only 14 per cent. of 63 cases in which the mesenteric arteries were obstructed and in 56 per cent. of the 31 cases in which the veins were involved. Admixture of blood in stools or vomit was observed in half the cases. In fully 75 per cent. of the cases only 3 of the above symptoms were evident. In one of his personal cases an anemic infarct was the cause of the trouble and this is the sixth case on record in which recovery followed resection of the part of the intestine involved. In 2 other patients, the presumptive diagnosis of obstruction of mesenteric vessels was shown to be erroneous at the operation. In treatment it is well to bear in mind that although in rare cases the intestinal infarct may be spontaneously absorbed, yet the serious secondary disturbances justify a prompt laparotomy in every case in which obstruction of the mesenteric vessels is suspected. He advises resection with primary union of the stumps, even if a long stretch has to be removed. He resected 9 feet of small intestine in a youth eight years ago, on account of volvulus, and the patient is still in good health. Extensive resection has as good prospects with mesenteric circulatory disturbances as with volvulus.

82. **Test for Blood.**—Kossa states that the technic which he describes is very sensitive, surpassing other tests in this respect, while it is simple and rapid. It is based on the principle that blood in an extremely diluted watery solution can be flaked out if some substance is added which reduces the solubility of blood in water. If, for example, 5 c.c. of defibrinated dog blood is mixed with 10 liters of distilled water it forms a 5 to 10,000 solution. To 10 c.c. of this solution 10 c.c. of 90 per cent. alcohol is added and the two fluids are mixed by gently swinging the test-tube, not shaking it; 5 c.c. of chloroform is then added and mixed in this same way. At the junction of the water and chloroform the blood shows as a precipitate of small red flakes. They show up better against a white background. The test is modified a little for urine; 10 c.c. of urine is diluted with the same amount of distilled water, then mixed with 5 c.c. of 90 per cent. alcohol; 5 c.c. of chloroform is then added and the whole is mixed by gently swinging the tube. It is then set aside to settle. If there is much blood a pink ring forms at the junction of the fluids. If not the supernatant fluid is decanted and a few more cubic centimeters of alcohol are added, when the pink flakes of blood become more apparent. If there is still doubt as to the outcome, the supernatant fluid is again decanted and a little diluted potash and one or two drops of yellow ammonium sulphid are added and the fluid is examined with the spectroscope. The lines show up better if the test-tube is held over a white background and the fluid examined from above, vertically. Any albumin present may flake out, but it is not red, and the physiologic elements of the urine are *not* precipitated.

83. **Bile Pigment Reaction in the Urine.**—Torday states that in examining the gastric juice of a jaundiced patient he obtained a red discoloration reaction with methyl violet instead of the expected blue stain of free hydrochloric acid. Study of this reaction shows that it is the result of admixture of bile pigment. He has utilized this reaction as a very sensitive test for the presence of bile pigment, especially in the urine. Comparison of this test with others in vogue showed that it gave positive findings with such minute proportions of bile pigment in the urine that the other tests were negative.

84. **Functional Diagnosis of the Heart Action.**—Ritook here describes comparative tests of the heart functioning by the Strasburger and v. Recklinghausen technics and v. Koranyi's method. The latter is based on the fact that the composition of the urine is influenced by the rapidity of the circulation. When the circulation becomes sluggish, as in case of failing compensation of heart defects, the elimination of chlorids suffers first and most, and when the circulation starts up again the elimination of chlorids increases first and most rapidly. As the freezing-point of the urine is the measure of the molecular concentration, the freezing-point divided by the chlorid content gives a quotient which rises and falls as the circulation is sluggish or rapid. The careful application of these methods reported confirms the value of the Koranyi quotient as an index of the functional capacity of the heart, especially when the person is put on a test regimen: supper at 6 p. m.; urine voided at 12 and again at 6 a. m., when 100 gm. of milk is ingested and urine is again voided at intervals of 90 minutes. Examination of the different portions of urine under these conditions gives a uniform basis for comparison.

85. **Orthostatic Albuminuria.**—Vas has examined 150 girls between the ages of 9 and 14 to determine the influence of curvature of the spine on orthostatic albuminuria. His findings confirm those of Jehle, mentioned in The Journal, Feb. 27, 1909, page 740, except they show that curvature of the spine is not the exclusive cause of orthostatic albuminuria, although it is an important factor in many cases by its interference with the circulation in the kidneys.

88. **Operative Treatment of Hay Fever.**—Blos reports three cases in which he cured the tendency to hay fever by resecting the anterior ethmoidal nerve on both sides to induce permanent anesthesia of the mucosa of the anterior part of the nose. The nerve was resected under chloroform or with local anesthesia plus morphin or with local anesthesia alone.

There is a distinct granulose reaction in the bacteria present when the digestion of starch or its absorption is interfered with. With a pancreatic affection the flora is strongly iodin positive. This iodin reaction is not only a more sensitive test for the digestion of carbohydrates than microscopic discoloration of the stool with iodin, but it also affords information in regard to the etiology and topography of various digestive disturbances, as he describes in detail.

117. **Present Status of Tendon Transplantation.**—Hohmann here reports the experiences at Lange's clinic at Munich with tendon transplantation, with twenty-six illustrations and discussion of the preferable technic. One of the impediments to fine functional results is the tendency to adhesions after the transplantation, and he gives directions how to avoid this, especially by making a canal for the transplanted muscle through the subcutaneous adipose tissue instead of below it. The results on the whole are encouraging and promise important progress in this line.

119 Improved Technic for Goiter Operations. (Die Knopflochverlagerung des Kropfrestes.) F. Hofmeister.
120 *Operative Mobilization of the Knee. (Operative Mobilisierung des Kniegelenks.) R. Klapp.

120. **Mobilization of Knee.**—Klapp declares that the problem of mobilizing the knee by an operation has not yet been effectually solved. Interposition of soft parts, after breaking up the ankylosis, mobilizes the knee, but does not make it stable. It should be capable of weight-bearing, and he thinks that this can best be accomplished by excising a wedge from the epiphysis of the femur. The wedge forms an angle of nearly 90 degrees, and is cut out entirely across the femur, as he shows in an illustration. The knee is bent beyond a right angle to the extreme limit and is held thus for a few minutes to correct the tension of the soft parts; then it is held at a right angle while the wedge is excised, the aim being to retain the connection with the tibia without modification. After the resection he nails the lower part to the upper stump, removing the nail six days later. A plaster cast is applied extending to the ankle. It is cut to the knee from the rear by the end of a week, to permit some movement, and is removed by the end of the second week. The movements are painful at first. The soft parts are passively stretched after the fourth week, not by massage, but by elastic traction; the patient sits on a chair and the leg is fastened by a rubber band to the leg of the chair. As no ligaments are severed there is not the least lateral movement. He has thus operated on two patients; one is already able to make active movements of more than 45 degrees, with a little larger passive range. The other has only recently been operated on.

125. **Renal Syphilis During Pregnancy and Confinement.**—Hirsch has recently reported three cases of renal syphilis, one being in a pregnant woman, and he here gives the details of this last case to warn obstetricians to be on the lookout for this syndrome. His patient was a woman of 35 with albuminuria and edematous swelling after the fifth month of her last pregnancy four years before. The kidney disturbances subsided for a time, but then there was pain in the right kidney region, with tenesmus but little urine. She grew thin and the kidney disturbances increased during her last pregnancy, which was complicated by hydrocephalus and ascites in the child. Notwithstanding the painful tumor in the right kidney region, there were no tube-casts, but merely epithelial cells in the urine. After delivery the patient was given potassium iodid for four weeks and all the symptoms disappeared; there has been no recurrence since. The husband recently applied for relief from violent headache in the vertex, which had resisted ordinary measures for five years. He also was given potassium iodid, and by the end of the fifth bottle was completely cured. Hirsch affirms therefore that a unilateral painful diffuse tumor in the kidney, with reduction in the amount of urine, but with large albumin content, speaks for a syphilitic affection demanding potassium iodid. It is well to bear this in mind in every case in which the ordinary treatment of assumed pregnancy kidney is not promptly effectual after delivery.

129. **Surgery of the Pancreas.**—Cappelli emphasizes the importance of the lymphatic connection between the bile passages and the head of the pancreas. A group of lymphatics from the gall-bladder unite in the head of the pancreas. This demonstrates the importance in treatment of chronic pancreatitis of draining the hepatic duct after removal of the gall-bladder as the most rational means of curing the pancreatic trouble. In acute hemorrhagic pancreatitis the gravity of the affection is due to the necrotic destruction of the pancreas rather than to the hemorrhage. Chronic pancreatitis consecutive to gall-stones is a well-individualized morbid entity, and the cure after effectual drainage of the bile passages proves its dependence on the lithiasis. The operation is more successful the earlier it is done, before glycosuria reveals disturbance in the internal secretion.

131. **Mental Disturbances with Brain Tumors.**—Osti concludes his study of this subject with summaries of 54 cases from the literature to confirm his assertion that early psychic symptoms, predominating over all the other symptoms of a tumor, are of the greatest importance for the diagnosis of a tumor in the frontal lobe.

133. **Addison's Disease and the Internal Secretions.**—Leonardi reports the clinical and autopsy findings in three cases; the morbid changes in the suprarenals were accompanied by corresponding changes in the other glands with an internal secretion, the thyroid, hypophysis and spleen—all of these were hypertrophied with evidence of hyperfunctioning. He does not regard Addison's disease as due to a single gland but to several participating in the process. The first symptom in one patient was tremor of the arms, probably the result of professional exposure to electric currents, the man's work being done under an electric light of between 15,000 and 20,000 candle-power. The effect of the Roentgen rays on glandular organs suggests that the light here may have affect the cervical sympathetic, the thyroid and the hypophy

92. **Pathogenesis of Rachitis.**—Sittler declares that rachitis occurs most frequently and in its severest form among bottle-fed children receiving too large amounts of carbohydrates, especially flour. Incipient rachitis can be cured by dropping the flour from the diet. The limits of injury from the flour and carbohydrates vary widely in different children.

93. **Influence of the Ductless Glands on Immunity to Infections and Intoxications.**—Lorand presents arguments to sustain the assumption that immunity to infections and intoxications depends on the possession of well-functioning ductless glands. They protect against factors that tend to shorten life, and may afford a more rational basis for the life expectancy in insurance. He cites as the most important causes that affect these glands and reduce the resistance to infections and intoxications, insufficient food, chilling, worry and sorrow, although all other factors detrimental to personal hygiene may cooperate. This assumption explains why children are so exposed to infectious diseases as these glands are yet imperfectly developed, while in the aged they have undergone senile modifications.

100 Physiologic Action of Carbonated Baths. (Neue Untersuchungen über die physiologische Wirkung der Kohlensäuregasbäder.) L. Fellner.

94. **Therapeutic Hypnosis.**—Becker reports successful application of hypnosis in a number of cases, but he never applies this technic until after absolute failure of all other measures. He does not induce the hypnosis by sensory means, but sits near the patient who is reclining on a sofa in a quiet room, he places two fingers on each eye, and suggests tranquil sleep by telling the patient to lie quiet, relax and rest. In a short time the hypnotic sleep is complete, with catalepsy. This phase is the most propitious for therapeutic suggestion. He insists that there is no mystical explanation of the condition, the whole being a psychophysical process distinguished merely by the acceptance of the suggestion while the inhibiting critical counter-suggestions are not aroused. As functional morbid phenomena are frequently associated with organic disorders, and as these functional symptoms may be the cause of the main discomfort, the therapeutic hypnosis is thus liable to benefit even in the organic cases. The psychogenic phenomena once banished, the patient pays no attention to the persisting organic disturbances and may be restored to comparatively satisfactory health. This is frequently the explanation of the benefit from a trip to a health resort. He cites a few cases in detail to show his exact method and its results. Traumatic neurasthenia frequently resists this therapeutic hypnosis and may recur after a transient improvement; the outlook is more favorable in cases of dread and phobias, obsessions, and in sexual weakness and enuresis of psychogenic origin.

110 History of Introduction of Salicylic Acid into Treatment of Acute Articular Rheumatism. (Einführung der Salizylsäure in die Therapie des akuten Gelenkrheumatismus.) O. Meltzer.

102. **Intra-Arterial Anesthesia.**—Oppel is convinced that local anesthesia will finally require an intra-arterial technic before it can be regarded as perfected. As a basis for research in this line, he reports experiments with cocain injected into the abdominal aorta and the femoral and carotid arteries. His technic is somewhat similar to that of Bier's venous anesthesia, illustrated in The Journal, May 1, 1909, page 1466, only he made the injection into the artery instead of a vein, thus going with the blood stream instead of against it, and not having to contend with the valves in the veins. One fact has been learned from this research, namely, that the fatal dose is eight or ten times as large when injected into an artery. It is evident that the broader the area of ramification the lesser the toxicity as the cocain is neutralized in an extensive arteriocapillary field like that of the abdominal aorta. Another Russian, Goyanes, has already successfully applied the intra-arterial technic in two clinical cases.

105. **Gynecologic Peritonitis.**—Hagen calls attention to the peculiarly mild nature of peritonitis when it originates merely from a local chemico-toxic process, such as results from the gradual spread of the inflammation from a suppurative affection of the ovaries or tubes which has been established for some time. As the pus germs find their way through the lymphatics to the peritoneum, the latter is enabled to summon its defensive forces to repel this gradual invasion. The symptoms may be tempestuous at first, but the peritonitis is not suppurative; it is merely a typical chemical peritonitis, accompanied by tympanites, but without rigidity of the abdominal walls. Palpation of the genitalia is easy, but very painful; it early reveals the source of the trouble. Another aid in the differentiation of this comparatively mild form of gynecologic peritonitis is that the onset so often coincides with the menses when the infection is of gonorrheal origin. Complete repose and other appropriate measures for expectant treatment generally suffice. He was obliged to operate only in two out of the fifteen cases in this category in his experience during the last few years. In all other forms of peritonitis in women, puerperal, from perforation, etc., the ordinary surgical principles of prompt intervention prevail, but this local chemico-toxic process permits temporizing. The acute process subsides relatively soon and order returns, but relics of the extinct chemical inflammation are sometimes found, in operating for a pyosalpinx, in the form of multiple, serous peritoneal cysts or adhesions even in parts of the abdomen remote from the uterus.

115. **The Diagnostic Iodin Reaction in the Intestinal Flora.**—Rodella refers to the staining reaction of bacteria in the stool which has been proposed as a means of differentiating them. His experience has shown that it is of little value for differentiating species, but that it is important as an index of

conditions in the intestines. A particle of stool on the object glass is mixed with the official compound solution of iodin and examined under the microscope. There is a distinct granulose reaction in the bacteria present when the digestion of starch or its absorption is interfered with. With a pancreatic affection the flora is strongly iodin positive. This iodin reaction is not only a more sensitive test for the digestion of carbohydrates than microscopic discoloration of the stool with iodin, but it also affords information in regard to the etiology and topography of various digestive disturbances, as he describes in detail.

117. **Present Status of Tendon Transplantation.**—Hohmann here reports the experiences at Lange's clinic at Munich with tendon transplantation, with twenty-six illustrations and discussion of the preferable technic. One of the impediments to fine functional results is the tendency to adhesions after the transplantation, and he gives directions how to avoid this, especially by making a canal for the transplanted muscle through the subcutaneous adipose tissue instead of below it. The results on the whole are encouraging and promise important progress in this line.

A group of lymphatics from the gall-bladder unite in the head of the pancreas. This demonstrates the importance in treatment of chronic pancreatitis of draining the hepatic duct after removal of the gall-bladder as the most rational means of curing the pancreatic trouble. In acute hemorrhagic pancreatitis the gravity of the affection is due to the necrotic destruction of the pancreas rather than to the hemorrhage. Chronic pancreatitis consecutive to gall-stones is a well-individualized morbid entity, and the cure after effectual drainage of the bile passages proves its dependence on the lithiasis. The operation is more successful the earlier it is done, before glycosuria reveals disturbance in the internal secretion.

131. **Mental Disturbances with Brain Tumors.**—Osti concludes his study of this subject with summaries of 54 cases from the literature to confirm his assertion that early psychic symptoms, predominating over all the other symptoms of a tumor, are of the greatest importance for the diagnosis of a tumor in the frontal lobe.

133. **Addison's Disease and the Internal Secretions.**—Leonardi reports the clinical and autopsy findings in three cases; the morbid changes in the suprarenals were accompanied by corresponding changes in the other glands with an internal secretion, the thyroid, hypophysis and spleen—all of these were hypertrophied with evidence of hyperfunctioning. He does not regard Addison's disease as due to a single gland but to several participating in the process. The first symptom in one patient was tremor of the arms, probably the result of professional exposure to electric currents, the man's work being done under an electric light of between 15,000 and 20,000 candle-power. The effect of the Roentgen rays on glandular organs suggests that the light here may have affected the cervical sympathetic, the thyroid and the hypophysis.

Later the process seems to have extended to the abdominal sympathetic and suprarenals. In another case, atrophy of the ovaries followed a pregnancy with premature menopause. Calcareous degeneration of the thyroid followed, with tuberculous infection later and fulminating suprarenal symptoms. The diseased suprarenals could not obtain help from the ovaries and thyroid and there was merely slight hyperfunctioning of the hypophysis as a defensive reaction. In the three cases, patients in the last stages of Addison's disease recovered their energy and the bronzing subsided under thyroid treatment. The thyroid was already modified and was inadequate to supplant the diseased suprarenals, but it only required slight additional aid from without to be able to counteract temporarily the destructive process in the suprarenals. The disease, the course, the outcome, the histologic findings, the research in the experimental field, all sustain the assumption that Addison's disease in its complete form is a general affection of the entire great sympathetic system.

134. **Exophthalmic Goiter.**—Ciuffini tabulates the details in four cases of exophthalmic goiter after strumectomy with special reference to the blood picture.

135. **Early Diagnosis of Cardiac Insufficiency.**—Rubino states that the viscosity of the defibrinated blood becomes much increased as one of the earliest signs of cardiac insufficiency. He offers a plausible explanation of this fact and suggests its importance for the early diagnosis.

139. **Formaldehyd Disinfection Without Apparatus.**—Walbum reports a series of comparative tests of various methods of formaldehyd disinfection. The most effectual and the cheapest is with the special disinfecting formaldehyd apparatus, but good results can be obtained with the potassium permanganate-formaldehyd technic, only larger amounts of the chemicals must be used than the directions call for. He found it impossible to obtain satisfactory results until he increased the amounts to 3.3 kg. potassium permanganate, 3.3 liters formalin and 3.3 liters water for each 100 cubic meters. Disinfection of passenger cars and hacks was one of his aims, and he describes the methods found most convenient. Strips of paper pasted along the crevices left unsightly marks, but it proved feasible to plug the crevices around doors and windows with cotton and the ventilators with cushions filled with cotton, while a special device closed the water-closets air-tight and permitted them to be filled to the top with a disinfecting fluid. The upholstery absorbs so much of the fumes that unusually large amounts are required. It was found possible to disinfect a hack in fifteen minutes with 500 gm. each of the permanganate, formalin and water, after doors and windows had been plugged with moist cotton. Staphylococci, diphtheria and typhoid bacilli were thus destroyed in the tests. After fifteen minutes the doors of the hack were opened and after five more minutes the zinc vessel holding the mixture was removed and another introduced containing 1.5 kg. of slaked lime in small pieces over which was poured a hot solution of 250 gm. of ammonium chlorid in 500 gm. boiling water. The doors of the hack were then closed again for fifteen minutes, after which the vessel was removed, the doors thrown open, and the vehicle was again ready for use in an hour or hour and a half. Full descriptions are given of the different tests and methods used.

141. **The Urine Sediment in Nephritis and After Sports.**—Christensen gives the tabulated details respecting the urine findings in 10 football players, 12 wrestlers, 27 athletes after their exercises, and a number of others—all showing that the urine sediment after these exertions resembles the sediment in severe nephritis. Half an hour's wrestling by a robust and healthy individual will bring fat into the sediment of the urine just as is observed in chronic nephritis, but evidently it is merely the result of the changes induced in the circulation by the violent exercise.

144 *Hypertrophy of the Heart in Nephritis. (Hjertehypertrofien ved Nefritis.) V. Scheel.

144. **Hypertrophy of the Heart in Nephritis.**—Scheel regards it as practically established that the heart hypertrophies in nephritis on account of the changes in the smaller arteries, compelling it to greater efforts. These changes in the arterioles are the result of the action of some still unknown substance circulating in the blood owing to the defective elimination by the kidneys of nitrogenous waste, and it is probably an important factor in the development of arteriosclerosis. Cystic kidney and hydronephrosis, interfering with the elimination through the kidneys, are also frequently accompanied by enlargement of the left ventricle. The substance in question may have some direct action on the heart itself, stimulating it to greater efforts, so that the right ventricle may hypertrophy also. Changes in the myocardium do not play much part in nephritis; as a rule the coronary arteries are not much affected. Death from heart failure is more frequent with secondary than with primary nephritis. In his 27 cases of nephritis after acute glomerulitis, 6 of the patients died from heart failure, while only one fatality from this cause occurred in his 20 cases of contracted kidney. Hypertrophy of the heart was constant in his glomerulitis cases, but was not encountered once in 15 cases of chronic parenchymatous nephritis.

DIET IN TYPHOID FEVER *

WARREN COLEMAN, M.D.
Professor of Clinical Medicine on Applied Pharmacology, Cornell University Medical College; Visiting Physician, Bellevue Hospital
NEW YORK CITY

The conclusions which I have reached concerning the food requirements of the typhoid fever patient are based on studies on the protein metabolism of the disease which have been carried out in Bellevue Hospital and the Department of Experimental Pathology of Cornell University, in collaboration with Dr. P. A. Shaffer, during the last two years.

I believe that the solution of the essential problems of the typhoid-fever diet will be found in the correct answers to two questions:

I. Shall the typhoid fever patient be given enough food to meet his energy requirements?

II. How much food may be considered necessary to fulfill these requirements?

It is obvious that the digestibility and general suitability of the various foods can not be ignored, and these will be referred to later.

I. SHALL THE TYPHOID FEVER PATIENT BE GIVEN ENOUGH FOOD TO MEET HIS ENERGY REQUIREMENTS?

Brief reference to the history of typhoid diets will assist us in finding the answer to this question.

Starvation was the accepted practice for centuries in fevers of all kinds, and included deprivation of water. Graves[1] (1835) convinced himself that, for want of food, the ill effects of starvation were added to the ravages of the disease and recommended a diet which at that time was considered revolutionary. The diet consisted of carbohydrate-water made from toast-crumbs, meat-broths and jellies. It is difficult to estimate the caloric value of Graves' diet, since exact quantities are not mentioned, but at the most liberal reckoning it furnished not more than 300 calories in 24 hours—the equivalent of about 10 ounces of milk. Graves' belief that patients were benefited by this meager diet was shared by the great Trousseau and other eminent men of his time. The next advance in the feeding of typhoid patients was due, according to Nichols,[2] to the teaching of the late Austin Flint. Flint popularized the milk diet (about 1870). The usual quantity of milk taken by a typhoid patient in 24 hours—2 quarts—furnishes about 1,400 calories. The milk diet remained unchallenged until 1892, when Peabody's[3] paper, questioning its suitability, was published. Since 1892 there has grown up a school of practitioners who advocate liberal diets. Among them may be mentioned Shattuck,[4] Barrs,[5] Bushuyev,[6] Fitz,[7] Mueller,[8] Manges,[9] Kinnicutt[10] and LeFevre.[11] Bushuyev is the only one of these authors who has mentioned the quantities of the various foods to be given, and, therefore, the caloric values of these diets are difficult to estimate. Bushuyev's diet furnishes approximately 2,000 calories a day.

Thus, in each of these three diet-periods, there has been an increase in the energy value of the food recommended—an increase of 1,100 calories a day from Graves to Flint and a further increase of 600 calories from Flint to Bushuyev. With each addition to the diet the statement has been made that the patients have been benefited. With respect to each addition, the profession as a whole has been perhaps too conservative.

Since the chief objections which have been raised to the liberal diets relate rather to the physical state of the food than to the amount of energy they furnish, no attempt will be made at this time to answer them.

The history of diets in typhoid fever, then, clearly indicates a steady, but very slow, tendency to increase the amount of food allowed to the patients. Only exceptionally to-day do we find physicians, once they have used the higher caloric diets, advocating a return to the older methods, and as a rule their arguments are based on questions of digestibility rather than on the energy value of the foods. McCrae[12] has expressed the opinion that more harm may result from overfeeding than from underfeeding, but he is evidently referring to the possibility of setting up digestive disturbances. A distinction must be made between properly nourishing and improperly feeding a patient.

Turning from the history of the typhoid diets and the claims which have been made for them, we may inquire whether there is evidence that definite harm may *come to a patient through partial starvation. It* is well known that partial starvation lowers the resisting power of healthy persons, and there is reason to believe that immunity to infective diseases is not so readily acquired when patients are undernourished. Healthy laboratory animals develop a better immune serum than those which are not robust. Ewing[13] believes that many of the clinical and pathologic phenomena in severe cases of typhoid fever are directly attributable to an autointoxication resulting from the excessive destruction of body tissues. Furthermore, Ewing and Wolf[14] state, in a recent study of the urinary nitrogen in typhoid fever, that "the most obvious conclusion of this study is the inadequacy of the diet used in these cases and of that generally employed in typhoid fever."

There is, therefore, strong experimental and clinical evidence in favor of giving typhoid patients sufficient food to meet their demands for energy.

II. HOW MUCH FOOD MAY BE CONSIDERED NECESSARY TO FULFILL THESE REQUIREMENTS?

In answering this question I shall consider, first, the energy value of the food. The relative proportions of protein, fat and carbohydrate to be employed will be referred to later.

One of the chief characteristics of typhoid fever, as we know it, is emaciation (Fig. 1). Losses of 25 pounds during the course of cases of even moderate severity are not uncommon, and as much as 50 pounds may be lost by patients during prolonged, severe attacks. If these losses concerned only fat and water, they would probably not be serious, but they involve muscle and other tissues as well. Losses of from 15 to 20 gm. of nitrogen a day, representing from ½ to ¾ pound of muscle, are not unusual. Scarcely any one would deny that these losses should be prevented if possible, provided the means taken for their prevention is not more dangerous than the losses themselves. The hunger of many patients during the course of the disease and of all patients during convalescence is probably Nature's protest against the practice of partial starvation. Patients who are well enough complain of it, those who are too ill to complain probably have even greater need for food.

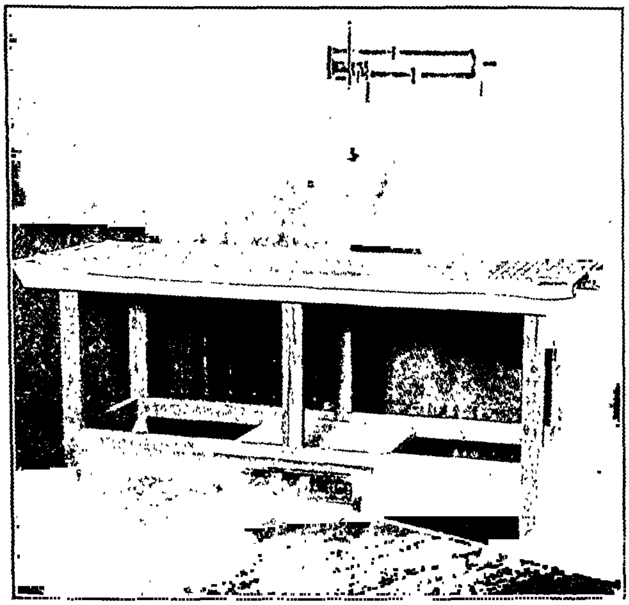

Fig. 1.—Apparatus for weighing bed patients constructed by hospital carpenter. The height of the table when placed on scales corresponds with that of the bed. The legs of table which just clear the floor prevent tilting.

The loss of weight in typhoid fever has been attributed to two causes: to the temperature and to so-called toxic destruction.

The Temperature.—The belief is common, even among the laity, that fever burns up tissues. Fritz Voit[15] and Linser and Schmid[16] have shown experimentally both in animals and man that pyrexia does increase metabolism. There is, therefore, a substantial basis for the common belief.

Toxic Destruction.—In addition to the febrile loss of body substances, there is a further increase in metabolism in the course of infective diseases which is due to the action of bacterial toxins. This is the so-called toxic destruction. The manner in which the toxins act is not definitely known.

Shaffer and I have found in our cases[17] that the losses due to both of these causes can be prevented by a high caloric carbohydrate diet. As no diet hitherto proposed for typhoid fever has furnished sufficient energy for the metabolic exchanges of the patient, we have concluded that the most potent factor in the losses of the disease is partial starvation.

We may calculate the minimum energy requirement of the typhoid patient as follows: A normal man at ordinary rest requires about 33 calories per kilo of body weight each day. According to Krehl,[18] the average typhoid patient requires a 25 per cent. addition to this in order to meet the febrile increase in heat production. This gives 41 calories per kilo of body weight per day or approximately 3,000 calories for a man weighing 150 pounds. It must be emphasized that this is the calculated minimum requirement.

If this calculation is approximately correct, then a patient weighing 150 pounds, taking 2 quarts of milk a day, is getting only 50 per cent. of his minimum requirement, and a patient of the same weight on a "liberal diet" is getting only 75 per cent. of this requirement. As a matter of fact, the discrepancies are even greater, since we found that the optimum requirement varied in different patients and at different stages of the disease, but was always greater than the calculated minimum. Our best results were obtained when the diets furnished from 60 to 80 calories per kilo per day, or 4,000 to 5,500 calories. In one case we reached 100 calories per kilo or 6,000 calories a day.

We have studied patients on a strict milk diet—2 quarts a day—and found that they lost from 5 to 12 gm. of nitrogen. These losses would cease, or at least be greatly reduced, when the energy value of the diet was raised. Forty-six patients altogether have been on our diet, with only one death. This was a case of ambulatory typhoid; the patient's pulse was alarmingly feeble on admission to the hospital, and he died a week later from what appeared to be acute dilatation of the heart. (I feel that this case might, with fairness, have been excluded from the total.) Many of the 46 patients suffered from very severe forms of typhoid fever. For example, the temperature ranged from 103 to 105 F. in one case and lasted 47 days, with a relapse of 27 days' duration. Some of the patients were kept almost in nitrogen equilibrium throughout the disease. It was not unusual for patients to weigh as much or even more when they were allowed to get up (usually about the fourteenth day of convalescence) as when they were taken ill. In one instance, the patient actually gained 2 pounds during a sharp relapse of 10 days' duration. In all instances, the patients appeared brighter and stronger and better able to fight the disease. The percentage of relapses was slightly lower than in another division of the hospital where the usual diets were employed. I do not feel disposed to make any statement as yet regarding the course and rapidity of convalescence. All of the patients left the hospital in excellent condition. Some of them I have been able to follow, and the impression I received was that convalescence progressed rapidly. But it is difficult to judge of this unless the patient can be seen frequently, which is manifestly impossible in the case of hospital patients.

Since the calculated minimum requirement of 3,000 calories diminishes but does not prevent protein loss, I would answer the second question by saying that a patient of 150 pounds' weight should be given food equivalent to 4,000 calories a day, but that the greater the energy value of his food, provided his digestive organs can handle it, the greater will be the sparing of protein and other body substances.

Diet.—The diet we used consisted, in the main, of milk, cream, milk-sugar and eggs. In addition, we allowed small slices of stale bread or toast, with as much butter as the patient wished. The daily quantities of these articles of food were about 1½ quarts of milk, from 1 to 2 pints of cream, from ½ to 1⅔ pounds of milk-sugar and from 3 to 6 eggs. It will be necessary to say a few words about each of these articles.

Fig. 2.—W. G. Blood culture positive. Very severe. Temperature 103-105 F. Duration of fever 47 days. Relapse of 27 day's duration. Ill for 3 weeks before admission. Said he had lost 15 lbs. Weight on admission, 151 lbs.; at end of first period, 140 lbs.; at beginning of relapse 144 lbs.; at end of relapse 140 lbs.: at first day up 154 lbs.; on discharge, 174 lbs. Picture was taken before patient was allowed out of bed.

Milk: I am convinced after much experience with it that milk, in moderate quantity, is not an undesirable constituent of the typhoid diet. When the quantity is excessive, it may unquestionably produce harm, but the argument that it forms an excellent culture medium for the typhoid bacillus in the intestine has been exploded by the investigations which have shown that typhoid fever is a bacillemia. Milk in the quantity mentioned has not produced tympanites in our cases. Occasionally milk curds have appeared in the stools and then the quantity of milk has been diminished or it was peptonized. A good average milk will furnish 740 calories to the quart.

Cream: Though cream furnishes a large amount of energy, it is not advisable, according to our present knowledge, to give more than one-third of the total calories of the diet in the form of fat. Fat in the food, if absorbed, will protect an equivalent amount of fat in the body. Fat protects protein also, but not so efficiently as does carbohydrate. Other objections to cream in large amounts are its tendency to upset the stomach and to produce diarrhea. Patients usually can take a pint of cream a day without difficulty. We have given as much as 42 ounces. In only one instance has the cream disagreed. This patient developed diarrhea when the quantity reached a quart a day. The diarrhea stopped immediately when the cream was withdrawn. The cream supplied at Bellevue Hospital contains from 25 to 30 per cent. of fat and furnishes 1,300 calories to the pint.

Fig. 3.—J. C. Blood culture positive. Severe. Temperature 101-105 F. Duration of fever 21 days. Weight, 12th day, 60½ lbs. (2 days after admission); 16th day, 58 lbs.; 18th day, 59½ lbs.; 22d day, 59 lbs.; 26th day, 58 lbs.; 28th day, 60 lbs. Picture was taken before patient was allowed out of bed.

Milk-sugar: Carbohydrate protects body protein better than any other foodstuff. For this reason a large proportion of the energy of our diet is supplied in that form. Starches can not be used in quantity because of their bulk and the consequent tax on the digestive organs. Therefore, it became necessary to select one of the sugars. We chose milk-sugar because it is not very sweet and not so likely to pall on the taste as other sugars, and because it does not so readily produce digestive disturbances. We have not found that it exhibited the laxative properties which have been ascribed to it; in fact, patients taking it often suffered from the constipation which is so common in typhoid fever.

The objections which we have found to milk-sugar are: some patients complain that it is too sweet; in some instances it produced nausea and vomiting, but more often vomiting without nausea, the stomach contents being simply regurgitated. When vomiting occurs, the milk-sugar should be stopped. As a rule, however, its administration may be resumed in smaller quantities after several days and the quantity then be gradually increased. In a few instances the milk-sugar has caused moderate tympanites. We have not had a patient who could not be educated to take it in sufficient amount to materially raise the caloric value of the diet. The method of giving the milk-sugar will be discussed later. Milk-sugar furnishes 4 calories for each gram, or 120 per ounce.

Eggs: While it has not been determined definitely how much nitrogen a typhoid patient requires in 24 hours, our results indicate that the optimum amount lies between 12 and 16 gm. One and one-half quarts of milk and a pint of cream furnish 11 gm. of nitrogen and we made up the deficit with eggs. A two-ounce egg supplies 1+ gm. nitrogen.

We chose eggs because they are easily digested and readily obtained. Meat and home-made meat juice are more likely to cause digestive disturbances. I have specified "home-made" meat juice because the consensus among scientists is that commercial meat preparations possess very little food value.[19]

Fig. 4.—P. Z. Blood culture positive. Moderately severe. Temperature 101-103.8 F. Duration of fever 34 days. Weight 6th day, 129 lbs.; 10th day, 132 lbs.; 15th day, 136 lbs.; 17th day, 135 lbs.. 21st day, 133 lbs.; 24th day, 132 lbs.; 27th day, 132 lbs.; 35th day, 130 lbs Picture was taken before patient was allowed out of bed.

It is important that the protein content of the typhoid diet be kept as low as is consistent with the nitrogen demands of the patient. In addition to digestive disturbances, the injudicious administration of meat may seriously disorder metabolism. It is well known that meat may cause the *febris carnis*. Ewing and Wolf[14] have recently found evidence in the urinary nitrogen to indicate that this "meat-fever" is due to the inability of the patient to digest and metabolize properly some alien proteins. They noted also in their cases this very important fact, that the *febris carnis* was soon followed by albuminuria, which, they suggest, may be the starting point of nephritis. Therefore, the caution may be repeated, to keep the protein content of the typhoid diet low during the disease and to allow meat sparingly early in convalescence.

Some Practical Considerations.—The diet which I have outlined is a difficult one to give to patients, on the whole rather more difficult than milk. Intelligent and reasonable persons, however, take it readily when the objects of the diet are explained to them. In other instances, patients are not told that the milk differs from what they have been accustomed to taking. The greatest difficulty has been experienced with adolescents who refused to take the diet because patients near them were allowed other food. When I have been convinced that the reason for not taking it was sheer stubbornness, I have insisted on carrying out the order. When I have even suspected that the diet was disagreeing with the patient, I have modified or stopped it, but always have cautiously resumed it (Figs. 2 and 3).

The food has been given at two-hour intervals, except that patients have not been awakened at night. The cream has usually been added to the milk, in the proportion of 2 ounces cream to 6 ounces milk, though a palatable ice-cream may be made with cream and milk-sugar. The milk-sugar should be given in small quantities at first—a tablespoonful to the glass of milk—and gradually increased to 4 tablespoonfuls. Many patients will take 2 ounces of cream, 6 ounces of milk and 2 ounces of milk-sugar several times a day, but this is a rich combination. At other times the milk-sugar may be given in tea, coffee, or cocoa, or it may be made with an egg into soft or baked custard. A milk-sugar lemonade may be given once or twice a day. If the water and sugar are boiled for two minutes before the lemon juice is added, 4 ounces of milk-sugar may be put into 8 ounces of lemonade. If the lemonade is not sweet enough, a tablespoonful of cane-sugar may be added. The eggs may be given soft boiled, soft poached or shaken up in milk, with or without whiskey.

While I believe that the foods mentioned must form the basis of the ideal diet for typhoid fever, much remains to be done in working out details. The greater the variety and the more palatable the dishes presented to the patient, the more content will he be to adhere to the prescribed diet. We have not yet been able to devote much time to the selection of variety in foods and dishes, but this is one of the questions which soon will engage our attention.

CONCLUSIONS

1. The practice of partial starvation, at present followed in the treatment of typhoid fever, is highly detrimental to the patient's welfare.

2. It is not only desirable but necessary that the typhoid patient be given sufficient food to cover his energy expenditures.

3. The amount of food required for this purpose will vary with different patients, but may be estimated approximately on the basis of 40 calories per kilogram of body weight per day.

ABSTRACT OF DISCUSSION

Dr. Max Einhorn, New York: The principles contained in the paper were recognized as far back as Graves, but they were not carried out as by Dr. Coleman. Since the days of Hippocrates it has been customary to subject these patients with fever to starvation diet, giving only water and barley-water, and under this rest treatment the patients felt quite comfortable; this method of treatment was carried out up to the time of Graves, who began to feed his typhiod patients with milk. The Hippocratic principle of rest was correct in caring for patients with diseases which run a short course, or last but a short time. Take an adult, with pneumonia, for instance, who is in good condition, the disease will last but five, six or seven days, the loss of a little flesh is not going to do him any harm; in starvation treatment may be carried out. The only important point that should be borne in mind and not forgotten is that these patients should have plenty of water. Individuals may go without food for a short time, but they can not stand the loss of water for even five, six or seven days. They can stand twenty days, loss of food, provided they are given plenty of water. But if we extend this principle a little further to patients with typhoid fever we then begin to see harm in the system. Typhoid fever lasts two, four, five or six weeks, and if we try to extend that principle the organism loses too much and irreparable consequences result to the system caused by the great loss of flesh. For that reason Graves believed that these patients should not be starved; he believed that they should receive nourishment and that one of the best substances for this was milk. Since then milk has been given to patients with typhoid fever, except perhaps when some fanatics give the starvation treatment. Twenty-five years ago, when I was house physician in a hospital, patients with typhoid fever were given a diet consisting particularly of milk, broths and raw eggs. Ten ounces every two hours were given, and also plenty of water and lemonade. With that diet, although we could not keep up the weight, we did prevent some loss. We gave occasionally a soft diet and farinaceous foods. What is new in Dr. Coleman's report is that he has succeeded in checking this loss of weight during the typhoid fever period. That has not been done before. During that period the organism requires more and more calories to replace the loss caused by the increased oxidation; the patient requires forty instead of twenty-five or twenty-six calories. Dr. Coleman has succeeded and we must follow his example and feed patients suffering with typhoid fever.

---

[19] Bull. No. 114, Bureau of Chemistry.

DR. THOMAS A. CLAYTOR, Washington, D. C.: For five or six years I have been feeding my typhoid fever patients along the lines advised by Dr. Shattuck and I agree with Dr. Coleman in his statement that when a physician has once fed these patients he will never be likely to return to the starvation diet. I believe that typhoid fever patients are more likely to recover when fed than when starved. They are far more contented. One of the most trying experiences with which these patients have to contend is hunger. When fed they are comparatively happy, they are much stronger, they convalesce more rapidly. Instead of being reduced to skin and bones they get up in good physical condition and are able to return to work much earlier, which, to the working man, is a very important thing. I certainly have not seen any more instances of hemorrhage or of perforation among the patients liberally fed than in those on liquid diet. I feel convinced that within the next ten years liberal feeding will become the rule rather than the exception in the treatment of typhoid.

DR. ARTHUR K. STONE, Boston: In a series of over fifty typhoid patients treated by me last summer at the Massachusetts General Hospital the diet used was much more mixed than that used by Dr. Coleman and was the diet suggested a number of years ago by F. C. Shattuck. It represented about 2,000 calories and my patients did as well as did Dr. Coleman's; there was only one death in the series. On the whole, the patients behaved very well on that diet and lost but little weight, but I debated whether it would not be wiser to add sugar of milk or in other ways to increase the caloric value of the diet; but as they were doing so well I concluded that this would not be necessary. However, to make sure, I invited Professor Follin to see these patients with me, requesting him to suggest whether it would be wise to increase the caloric value of the diet. He said he saw no reason why I should change from the diet I had been using. Practically no drugs were used in the treatment of these cases and the baths were light sponges.

DR. A. JACOBI, New York: Dr. Coleman is to be congratulated on his results, which, with that diet, I should not expect. I am greatly astonished at the good results he obtained. His diet was milk and, I hope, good milk. He has been very fortunate and I have not the slightest doubt the patients did very well; but what he told us certainly does not agree with what we know. It looks almost impossible to expect a healthy person, far less one with typhoid fever, to digest as much food as his patients did. I have never seen more disorders of digestion with indicanuria, acetone and diacetic acid in the urine than in patients who consumed a great deal of fat in that shape. Moreover, his patients taking so much fat took, at the same time, much milk undiluted and unmixed; my patients could not take it without becoming ill. I know that few children will stand an exclusively milk diet very long. It is true that patients will stand a great deal, but we should not contribute to their suffering. I wish to state that it is impossible for an average intestine to digest an unmixed cream to that extent. We cannot go into the physiology of digestion at this time, but I know that both adults and children, healthy or diseased, will bear milk that is diluted with cereal better, particularly in fevers in which the gastric secretions are lower than before the individuals were taken ill. In typhoid fever I would rather furnish the patients with 2,500 calories than 3,000, 4,000 or 5,000. It seems to me that Dr. Coleman, in his good wishes for the patient, has gone too far. Yet he says he has lost but one patient, and I think that other conditions in the hospital must have been extremely favorable and the patients well cared for. I congratulate him on his results, but I wish to give warning that we should be very careful in fat feeding to the extent that he has proposed to us. If a cereal is mixed with the milk, it will be more digestible. For many years I have not given pure milk in typhoid fever; I always mix it with rice-water or barley-water or other cereals or gelatin. I may not agree with Dr. Coleman's views, but I cannot gainsay his results, which are almost unprecedented. What I have said, however, is intended as a warning only.

DR. JAMES M. ANDERS, Philadelphia: I think it is a significant fact that general practitioners no longer pursue a starvation diet in the treatment of typhoid. Certain dietetic principles should be kept in mind in connection with the management of typhoid fever, and this remark applies to other infections as well. First of all, we should consider the proteid substances and recollect that the energy they represent is not all utilized by the system. For example, too much proteid food favors putrefaction in the intestinal tract, and with this there is brought about increased gravity of the case, especially in the direction of local symptoms. On the other hand, we should recollect that the energy represented by carbohydrates and fats is entirely utilizable within the system; therefore, we should give a certain amount of carbohydrates and fat to typhoid patients. This is what Dr. Jacobi has just hinted at in connection with the giving of milk. It should be remembered that one object of the dietetic treatment is the preservation of the tissues of the body and the prevention of emaciation which would otherwise occur. Fats, however, will not do this, but the carbohydrates will do it. Some of Dr. Coleman's success in maintaining the bodily weight of his patients so well may have arisen from the use of carbohydrates which were easily digested, and particularly the milk sugar which he recommended. It seems to me that his main suggestions are excellent ones and could be profitably followed by the general profession. The preservation of tissues, however, can only be accompanied by the use of carbohydrates.

DR. JAMES B. WALKER, Philadelphia: I have been very much interested in Dr. Coleman's paper because I have feared that increase in feeding of typhoid-fever patients may go too far to the other extreme. I believe that Dr. Coleman's results are thoroughly honest and true, but I fear, with Dr. Jacobi, who is always right, to give as much cream to a typhoid patient as Dr. Coleman has done. One article of diet which I think should not be given is starch. Starches are digested in the small intestine largely, as in the absence of chewing, insalivation is almost *nil*. Those who advocate a crust of bread or toast or other starchy food make a mistake in that they throw work on a part of the bowel that is not prepared to do it. I have found calves'-foot jelly—freshly prepared from the calves' feet and not made from the gelatin of the shops too often containing the clippings from tanneries—an appetizing and digestible addition to the typhoid diet. I should like to add this to Dr. Coleman's list. I have given as much as one pint daily. As gelatin is believed to be antehemorrhagic, it may help to avert this dangerous complication. I want to advise against the use of starches for what seems to me good physiologic reasons, to advocate the use of calves'-foot jelly as an addition to the diet, and to protest against too varied and liberal feeding of patients affected with typhoid fever.

DR. D. L. PARKER, Detroit: The tendency to more liberal feeding in typhoid is establishing itself rapidly, and it seems to me that the principle that underlies the whole scheme is the return to the mode of living which is natural to the patient, so far as his condition will permit. Certain articles of diet must be eliminated, such as starches, which are digested in the small intestine, as Dr. Walker stated. One of the most important things to remember is that the natural diet contains salt, and, as a rule, the diet given to patients with typhoid fever contains very little salt. For a number of years it has been my practice to see that these patients receive as much salt at least as on an ordinary diet. Another important thing is to have sufficient time between the feedings. It has been found in the forced feeding of tuberculous patients, for instance, that the taking of food at intervals of four or five hours is very much better for these patients than if the meals are closer together. No person here in this room would think of taking food every two hours. I think the giving of food should be at longer intervals. Sufficient time should be given for the digestion of one meal before another is given.

DR. WOODS HUTCHINSON, New York: Nothing illustrates the progress of medicine better than the treatment of typhoid fever. Over sixty years ago Graves of Dublin chose as his epitaph "He fed fevers." Prior to this, blankets were placed over these patients, they were given very little food; even with high temperatures they were not allowed much water and no fresh air; the windows were kept closed; cold water to drink was regarded as deadly; and only lukewarm slops were permitted; in fact, the patients suffered almost as much from what was done for them as they did from the disease. Six years ago I began to use a liberal diet in my cases of typhoid fever, and the results have been the same as Dr. Coleman's. I had not the courage to carry it so far as Dr. Coleman has done, but the patients were given an abundance of tender meat, broths, jellies, crackers, toast, ice-cream, etc., and the results were excellent, not only as to keeping up the weight and strength of the patients, but also in preventing that condition of collapse after the fever subsided and the violent convalescent appetites which hitherto had craved such things as corned beef, beans and cold slaw. The patients made more rapid recoveries, had fewer complications and the results as a whole were very good. We think too much of the risk to the damaged intestine from liberal feeding in this disease, and regard typhoid fever as an intestinal disease too exclusively. Typhoid is a general disease, and, as has been shown, those patients who have been fed liberally, instead of suffering more from putrefactive changes in the intestines and tympany, have less of these changes, and fewer complications than those who are underfed. We are coming to see that many of the later symptoms that occur in the disease are due not so much to the actual toxic products of the bacilli as to the poisons generated from the broken-down tissues of the patient. Many of the symptoms occurring late in typhoid fever are not so much to the disease itself as to the mistaken method of treatment, among which starvation ranks high. There is a risk in withholding food as well as in giving it.

DR. WARREN COLEMAN, New York: I did not foresee the nature of the questions which have been asked me or I should have requested more time of the chairman for my paper. One cannot deal adequately with such a subject as diet in typhoid fever in ten minutes. For lack of time I cannot answer all the questions that have been raised in the discussion. I feel, however, that I must attempt to reply to Dr. Jacobi.

The first thing I would say, and say emphatically, is that I did not experiment with patients in a way that was not thoroughly justifiable. Every increase made in the amount of milk-sugar was carefully controlled by observation in the hospital and by examinations in the laboratory of experimental pathology. Every increase made in the amount of fat was controlled in the same fashion. When there was reason even to suspect that the food was not agreeing with a patient, that particular article of food was stopped or diminished in quantity. I think that Dr. Jacobi perhaps has gained a wrong impression with regard to the amount of cream given. The usual quantity was one pint; sometimes as much as a quart; and in one or two instance even more. I did not observe any digestive or intestinal disturbances in any patient who was fed on this relatively large amount of cream except once; diarrhea occurred in that instance. The cream was stopped and at once the diarrhea ceased. Cream was not given again to this patient. The stools of all the patients were watched very carefully. There was no evidence that the cream was not, for the most part, utilized.

I am convinced that the principal question regarding the typhoid diet is whether it is desirable to let a patient live on his own tissues when it is possible to protect his tissues by giving him enough food. I have not yet worked out all the details of the diet. It has been estimated that gelatin may replace protein to the extent of one-fifth of the daily need of nitrogen. I started out to determine whether by giving a patient a sufficient number of calories to cover his expenditures, I could protect the body tissues. This was accomplished. In future I shall work in part on more practical problems, such as the varieties of food which may be given and the proper ways to prepare them. I did not follow the plan of giving large amounts of water, but was guided chiefly by the desires of the patients.

The patients are weighed on a long table, which, when placed on the platform of the scales, corresponds with the height of the bed. The weight is obtained without more disturbance to the patient than moving him from one side of the bed to the other.

INTRADURAL TUMOR OF THE MID-DORSAL CORD

OPERATION: COMPLETE RECOVERY OF SENSATION AND PARTIAL RESTORATION OF MOTION *

JULIUS GRINKER, M.D.
Professor of Nervous and Mental Diseases in the Chicago Postgraduate Medical School, Assistant Professor in Clinical Neurology, Northwestern University Medical School, Consulting Neurologist to the Cook County Hospital, Chicago, the Cook County Hospital for the Insane and the Cook County Infirmary at Dunning, Ill.
CHICAGO

The era of spinal tumor surgery began in 1887 when Gowers[1] correctly diagnosed and Horsley successfully removed a tumor from the mid-dorsal cord. The operation was followed by almost complete recovery of sensation and motion. Since the publication of this remarkable case, in 1888, neurologists and surgeons have vied with each other in their efforts to improve the neurologic and surgical technic of the diagnosis and surgery of spinal tumor.

Although many patients have been rescued from early graves and others have been restored to perfect health from a state of invalidism, yet the total number of complete and partial recoveries is not so large as to make the report of a single case superfluous. The diagnosis in some instances is extremely easy and certain, while in others it can never reach beyond a probability. The difficulties in diagnosis have been sufficiently set forth in the instructive article by von Malaisé,[2] the complete monograph of Bruns,[3] the lucid reports of F.

In my remarks at the conclusion of the following case report I shall briefly allude to the literature bearing on cases of spinal tumor in which operation has been performed.

REPORT OF CASE

Patient.—B. F., a working girl, aged 23, was first seen at the request of Dr. A. Goldspohn on Dec. 17, 1906.

Family History.—The parents were living and well; the grandparents on the mother's side died of old age; on the father's side they lived to middle age; their death was due to causes other than tuberculosis, malignancy, or vascular accident. An only brother and a sister were healthy. The family was remarkably free from functional and organic nervous disease.

Personal History.—The patient was born in normal labor and during infancy and early childhood had been free from serious disease. With the exception of an attack of typhoid at 12, measles and pertussis at 13, her health had been good until the beginning of the present illness. Her menses were regular, habits correct; there was no trauma or evidence of venereal infection.

Onset and Course of Disease.—Early in 1906 (January or February) the patient began to experience attacks of pain in the right hypochondriac region, which subsequently became more or less persistent. Occasionally the pains radiated into the epigastrium and produced a sensation of nausea, accompanied with eructations. It was the latter circumstance which first induced her to seek medical assistance. For some time she was treated for dyspepsia and neuralgia. Later an osteopath was consulted who endeavored to reduce a supposed displaced vertebra. In spite of all treatment, however, the symptoms continued to progress. The pains, which were at first almost entirely confined to the right half of the body, soon began to invade the left side, and in less than two months had nearly encircled the trunk at a height of one or two fingerbreadths below the nipples. Though there was considerable variation in the intensity of the pains, they were never entirely absent. The upper portion of the trunk, the face and upper extremities were at no time the seat of sensory disorder, but several weeks after the beginning of the disease, fatigue and numbness were complained of in the lower extremities, and these sensations had a tendency to become more or less constant. On Sept. 23, 1908, after having retired for the night, the patient awoke feeling numb and stiff in the left leg from the knee downward. When she stepped out of bed to ascertain if she could still walk, the discovery was made that the left leg dragged and was partially paralyzed. There was considerable improvement in this limb on the following day, but the right leg had meanwhile become similarly affected; the latter grew rapidly worse and within three days was paretic. One week after these motor disturbances a feeling of tightness appeared about the waist and all sensation was abolished below the umbilical line. The sphincters were somewhat affected. The patient could then still walk without support, but was obliged to take rather small steps, as the feet seemed glued to the floor. At this period of the progress of the case she entered a hospital where she received vigorous antispecific treatment for about ten weeks. It was while under such treatment, about three weeks after the first motor symptoms had appeared, that the left and, soon afterward, the right leg became completely paralyzed. With the paraplegia there appeared more marked muscular twitchings and jerkings, which had for some time previously been the cause of considerable discomfort. In addition there were burning sensations in the paralyzed parts. The bladder and rectum subsequently became paralyzed. Her condition continuing to grow worse, the relatives caused a transfer to the Evangelical Deaconess' Hospital, where she became a patient of Dr. Goldspohn, who kindly referred the case to me for an examination. This was made on Dec. 16, 1906, and the following notes taken:

"*Examination.*—The patient, a well-developed girl, weighing about 150 pounds, of average height, occupies a recumbent posture and answers questions intelligently. But for the occasional demonstrations of pain caused by recurrent muscular spasms in the lower extremities, she gives one the impression of perfect health. Examination reveals normal findings in heart, lungs and abdominal viscera; the pulse is soft, regular and 75 beats per minute. Blood and urine normal. Pupils are equal, respond to light and in accommodation. Vision is unimpaired and eyegrounds appear normal. Glandular enlargements or evidences of neoplasm can not be discovered on her body.

"Motion: Eyes, face, neck and upper extremities are not involved; in marked contrast with these organs are the parts below the nipple line; here everything seems lifeless. The abdominal muscles are paretic and there is a condition of "lead-pipe" rigidity in the spastic lower extremities. From time to time the legs are seen to draw up and slowly to relax; voluntary control over the muscles is completely lost. The sphincters are distinctly paretic. The bladder empties itself periodically without the patient's knowledge. The bowels are absolutely constipated; several enemas are usually required to cause a partial evacuation.

"Reflexes: Normal in eyes, face and upper extremities. Abdominal reflexes are absent. The patellar and ankle-jerks are pathologically exaggerated; there is distinct bilateral rectus and ankle clonus. Babinski, Oppenheim and Gordon signs are promptly obtained.

"Sensation: 1. Tactile sensation is abolished up to a point which corresponds on Seiffer's charts to the space midway between the fifth and sixth dorsal segments on the right and to about the sixth segment on the left side anteriorly (Fig. 1). Posteriorly tactile sensation is lost up to about a line indicating the sixth dorsal segment on the right and to about one-half segment below this on the left side (Fig. 2).

"2. In a small strip below the upper limit of tactile anesthesia pain and temperature sense are still preserved (areas shaded lightly in Figs. 1 and 2).

"3. There is a somewhat larger area below the one last mentioned in which the pain sense is still preserved, while other sensory qualities are lost (circles in Figs. 1 and 2). Sensation seems to have suffered first and most in tactile conduction, then the temperature qualities appear to have yielded and last of all the pain sense has succumbed."

Diagnosis.—A history of unilateral pain gradually becoming bilateral, followed by motor paralysis of first one lower extremity, then of the other, with sphincter and sensory paralysis added, presented the classical symptom-complex of spinal tumor. The negative findings above the line of beginning anesthesia certainly excluded diffuse cerebrospinal disease. The relatively slow evolution of symptoms was against the diagnosis of acute transverse myelitis and in favor of slow compression of the cord by tumor. Syphilis and tuberculosis had still to be considered. But there were no stigmata of congenital or acquired lues and no evidence of tuberculosis anywhere on the patient's body. Neither was there a history of trauma or of infection. Having decided that there was a tumor of the cord, the next task was to localize it. This was comparatively easy. Sensory disturbances of any kind being found opposite a line midway between the fifth and sixth dorsal segments, the upper end of the neoplasm was probably situated opposite the spine of the third dorsal vertebra.

In the determination whether the tumor was extradural, intradural or medullary in character, I was influenced by the following considerations:

1. There were no neoplastic formations anywhere in the body; there was no deformity of, or tenderness in the vertebræ. The pains were, in the beginning at least, not agonizing, constant or of long duration. These negative findings spoke strongly against the existence of an extradural tumor.

2. The early presence of root irritation (pain) and at the same time the absence of cord symptoms make the diagnosis of intradural tumor at least improbable; for in such tumors the rule is for cord symptoms to appear early and for pain to come late.

My diagnosis was: Spinal tumor, probably intradural and situated at or about the spine of the third dorsal vertebra.

Immediate operation was advised.

Arch. f. klin. Chir., 1907, lxxxiv, [illegible].

My colleague, Dr. Goldspohn, concurred in the diagnosis and was ready to operate, when for some unknown reason the patient's friends moved her to Wesley Hospital and entered her there as a ward patient. While at this hospital she was assigned to Dr. S. C. Plummer, the surgeon on service, who kindly referred the case to me for a neurologic opinion. After a re-examination, finding that no material change had occurred in her condition, I again concluded that a laminectomy was indicated. Dr. S. C. Plummer performed the operation on Jan. 4, 1907. He has kindly permitted me to abstract the following notes from his surgical report of the case before the Chicago Surgical Society, May 8, 1908:

Operation.—Patient was placed in the semiprone position on the left side. Ether anesthesia was used. The incision was made in the median line of the back, beginning just below the seventh cervical vertebra and extending downward to the seventh dorsal spine. The muscles were cut away from the sides of the spinous processes from the first to the sixth dorsal vertebræ on the left side. Several vessels were clamped and ligated, and a hot laparotomy sponge was packed into the wound, while on the right side the muscles were separated in a similar manner. Hemorrhage having been checked, the vertebral grooves were now cleared with a chisel by using the spinous processes as a fulcrum and pushing the tissues away from the laminæ. The spinous process of the fifth dorsal vertebra was now cut off with a bone-cutting forceps, and the ligamentum subflavum between it and the fourth dorsal vertebra severed with a knife. A special laminectomy forceps was used to cut away part of the laminæ of the fourth dorsal vertebra and the remainder was removed with the rongeur forceps. The dura, which now lay exposed from the lower border of the first to the upper border of the sixth vertebra, appeared normal in color; nothing abnormal could be felt on palpation. Pulsation seemed normal, but it was stronger in the upper third than in the lower two-thirds. This extensive exposure of the dura is explained by the circumstance that, having uncovered three cord segments and finding the dura seemingly normal, we believed an error in localization had been made. It was therefore decided to snip off another spine. When consequently the fifth vertebral spine had been removed and the dura still appeared normal, it was thought best to open it and search for the tumor. The patient's head was now somewhat lowered and the dura opened in the median line. Opposite the third dorsal spine a tumor was found lying between the membranes and the cord posteriorly and somewhat to the right. Using the handle of the knife this was easily delivered and the small pedicle broken off. While its exact attachment could not be definitely ascertained, it appeared to spring from the inner surface of the dura. The anesthetist noticed that the pulse, which up to this time had been but little above the normal, suddenly became very fast and difficult to count. The dura was now closed with a continuous suture and the muscles brought together with interrupted catgut sutures, leaving a space for a gauze drain down to the dura at the upper and lower extremities of the wound. The skin was closed with silkworm-gut sutures, a secondary suture being used at each end of the drain. In forty-eight hours one gauze drain was removed and in seventy-two hours the remaining one, secondary sutures being tied after removal of the drains. Aseptic healing throughout.

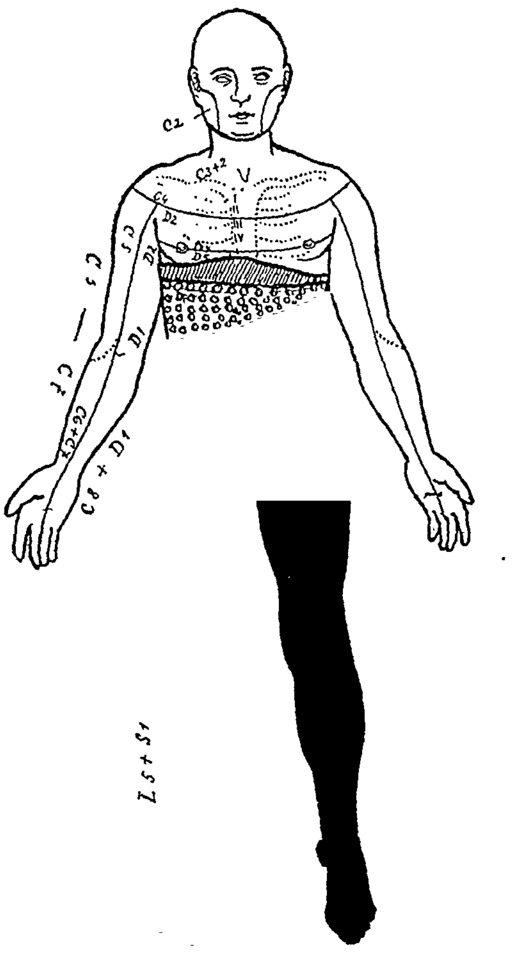

Fig. 1.

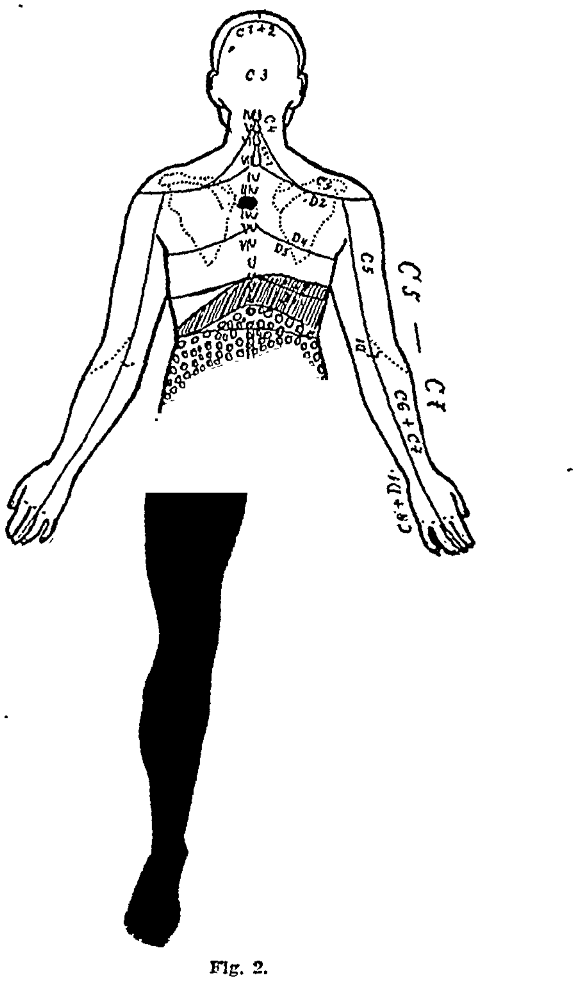

Fig. 2.

Figs. 1 and 2.—In both figures, the black space signifies total loss of all qualities of sensation; the circles indicate loss of thermal and tactile sensation; the shading denotes mere loss of tactile sensation. In Figure 2 (the back view), the heavy dot shows the highest border of the tumor.

Pathologic Report.—When examined macroscopically the tumor appeared reddish-yellow, was rather soft in consistency and measured 3 cm. in length, 0.8 cm. in its widest diameter and 0.2 cm. in thickness. The microscopic examination was made by Prof. F. R. Zeit, of the Department of Pathology at Northwestern University Medical School, who kindly reported on the tumor and pronounced it a typical fibromyxoma.

Postoperative History.—Immediately after operation the patient complained of severe pain in the back and over the entire lower half of the body. The pains somewhat subsided after two or three days and then became localized in the back and legs, where they remained for several weeks. Improvement occurred in the following order: Within twenty-four hours after operation the temperature sense showed signs of recovery; it was noted that hot-water bottles applied to the feet caused a disagreeable sensation. In less than a week after the operation the patient experienced a feeling of discomfort from a full bladder. Within two weeks she could distinguish between extremes of temperature. After three weeks painful stimuli, such as pin-pricks, were perceived as disagreeable. Tactile sensation and fine discrimination, as well as correct localization, of touch were very slow in returning. It was probably one year before the patient's sense of position and fine localization of touch were restored to normal. Although perfect recovery of all forms of sensation occurred within the period stated, it was quite different with motion. It will be recalled that the patient was completely paraplegic at time of operation; all motion in legs and toes was entirely abolished. Signs of return of motion appeared about six weeks after opertion. She could then flex the left big toe; somewhat later she gained control over the small toes of the left foot. Slowly and only after many months did a slight degree of motion return in the feet, but the thighs and legs remained spastic. For a long time one could still see the spasmodic movements of the legs on the thighs, which would only with great difficulty be passively extended. This condition gradually improved, but the patient never walked again.

Repeated examinations, made at intervals of three months each, revealed practically the findings as stated.

An examination made Feb. 20, 1909, showed: Good physical condition. Sensation and sphincters perfect. In the sphere of motility considerable improvement was noted; the patient could now use the feet and legs in operating a sewing machine several hours in succession. She was also able voluntarily to flex the legs against the thighs, full length. Flexion and extension of feet and toes could be performed fairly well. With some effort extension of the left leg was possible with the thigh flexed; extension of the right leg with the thigh flexed was only partial. For a few moments she could stand when supported by her upper extremities. She had not attempted the use of crutches because of her present faith in Eddyism, which forbids the use of such physical artificial aids.

Examination on May 22, 1909, yielded practically the same findings as previously. She had been persuaded to try crutches, but they did not sustain her weight, owing perhaps to her inability to extend the legs completely, slight contractures having formed in the knee joints. By means of orthopedic measures I believe her condition may be considerably improved.

REMARKS

The case presented a typical classical picture of intradural tumor in the upper dorsal cord, not unlike the first case with successful operation by Victor Horsley.[1] In that case, however, the neuralgic state was protracted over a period of four years, from 1884 to 1887. In this case the period of root-irritation lasted seven or eight months. The pains, for a time at least, were distinctly localized on the right side, and, as the tumor enlarged in width, pains also appeared on the left side. Eight months later cord symptoms were very much in evidence, and, as in other cases, the most vulnerable motor tracts suffered before the more resistant sensory strands. A further similarity of this case with that of Gowers-Horsley is seen in the fact that the tumor on microscopic examination proved to be a fibromyxoma; but in this case, unlike theirs, the tumor had grown rapidly.

Considering the final outcome, how should this case be classified?

According to Collins,[7] it will have to be classed with the partially successful cases. In Collins' excellent article on spinal cord tumors he notes that an operation is considered successful when there is cessation of pain and recovery of motor power; partially successful when there is relief from pain, cessation of progress of the case, and slight regain of motor power; unsuccessful, when followed by death within a few weeks. This patient showed complete recovery of sensory functions, some regain of motor power and no return of symptoms two and a half years after operation.

Had the case been diagnosed before degeneration occurred in the motor tracts it would in all probability have found a place among the completely successful cases. From the history it is apparent that a positive diagnosis of spinal tumor could have been made at least three months before operation, yet ten weeks had been lost in treating the patient for syphilis. This is all the more regrettable since we know that gumma of the cord membranes is rare, and when found should be treated surgically the same as other tumors.

In a perusal of the recent literature on spinal tumor we discover—in marked contrast with the earlier publications—that cases are now diagnosed and patients operated on much earlier than formerly, with the inevitable result that the percentage of recoveries is becoming larger. Recent conservative estimates place the proportion of partial and complete recoveries after operation at 50 per cent. This has become possible only through the combined efforts of neurologists and surgeons, the former of whom have made spinal localization comparatively easy, while the latter have simplified and improved the surgical technic.

The wide interest which is at present being taken in surgical neurology is largely a result of the awakening to the possibilities of surgery, particularly of the peripheral nerves and spinal tumors. Already in 1895 M. Allen Starr,[8] after analyzing 123 tumors of the cord, argued that an early diagnosis of spinal tumor was possible; that removal could be accomplished without injury to the cord; and that the operation itself was not one of great danger. He considered that in nearly 75 per cent. of cases spinal tumors could be operated on successfully and he expressed the opinion that future statistics should show recovery in a much larger proportion of the cases than they did at that time. Considering that Bruns[9] in 1897 could collect only 20 cases of spinal tumors operated on, and Bregman[10] as late as 1906 could find only 50 cases of operation, it was remarkable that Stursberg[11] in his report could make the statement that up to 1908 he had already been able to collect 119 observations of extramedullary tumors operated on, in which diagnosis was proved either by operation or by autopsy. In the same year E. Flatau and N. Zylberblast,[12] who conjointly reported a case, estimated the total number of published cases of extramedullary tumor with operation to be 136, of which number 106 were intradural or extradural tumor, while 29 were cases of tumors originating from or extending to the vertebræ. It is noteworthy that Schultze[4] alone in 1907 could report on 14 cases with operation, in which number 6 patients made perfect recoveries and 2 showed improvement. Oppenheim[5] in the same year reports practical recovery in 4 out of 9 cases with operations in which he had made a correct localizing diagnosis.

[12] Flatau, E. and Zylberblast, Frl. N.: Beitrag zur chirurgischen Behandlung der Rückenmarkstumoren, Deutsch. Ztschr. f. Nervenh., 1908, xxxv, 334.

In spite of the great activity displayed in this branch of surgery during the last ten years, the total number of cases with operations up to date has not exceeded 150. And of this number the percentage of recoveries has only risen in the hands of the most expert surgeons when working conjointly with neurologists.

As for the total number of complete recoveries in cases with operation, Harvey Cushing,[13] who reports a case of his own with complete recovery, in 1904, could find only 10 other successful cases. But already in 1908 R. T. Williamson[14] found 51 published cases of meningeal spinal tumor in which operation was successful and had been followed by complete or almost complete recovery from spinal symptoms.

Several reasons have been advanced for the few recoveries so far recorded. One is that spinal tumor is not always easy to diagnose and localize; a failure to find the tumor usually means death by further inaction. A second important cause for failure is the discovery on the operating table that a correctly localized tumor is inaccessible, hence irremovable, as are most intramedullary and vertebral tumors. And, last but not least, the danger to life during and after operation is still great. While, therefore, by no means underestimating the dangers and pitfalls of surgical interference I am in thorough agreement with those who recommend exploratory laminectomy even in those instances in which the diagnosis is only probable. There should be less unwillingness on the part of the patient to consent to an operation if he is told that inaction will almost invariably destroy his life.

100 State Street.

ABSTRACT OF DISCUSSION

DR. PEARCE BAILEY, New York: I think we have a good many lessons yet to learn in the surgical treatment of spinal cord tumors. If one reads the list of cases in which the patients were successfully operated on, and those in which the operation has not been successful although the tumor has been found, the conclusion is inevitable that we ought to have a very much higher percentage of cures in these cases than we have at present. Many patients die of shock and sepsis and, I believe, from loss of cerebrospinal fluid. I am much in favor of doing operations in spinal cord tumors with the patient's head down, so that the loss of cerebrospinal fluid can be controlled. In a patient operated on in St. Luke's Hospital a short time ago, by Abbe, the tumor was found where we thought it would be. The operation was skillfully performed. There is no better operator for spinal cord tumors than Dr. Abbe; the operation took only 40 minutes; there was no hemorrhage, no infection, and yet there was considerable loss of cerebrospinal fluid. The operation was done on a horizontal table. Within a few hours the temperature began to rise and rose steadily to 103 degrees and 105 degrees, and within about 18 hours after the operation the patient died with a temperature of 107 degrees, with absolutely no infection and no cause discoverable except the loss of cerebrospinal fluid. I think this operation is a grave and serious one and very hazardous to life, and I think it should be undertaken with every precaution.

Dr. Grinker says that the surgeon in his case started by taking out 5 laminæ. I do not see any reason for that. I try to get the surgeons who operate for me to limit themselves in the start, if they will trust my localization, to two laminæ. And then it is easy enough to take out others if necessary. At first remove two laminæ, and then examine, and possibly the tumor will be found in one extremity. Then it is time enough to take out the extra lamina; and 3 is generally enough for the expression of the tumor. I think it is very important, because many patients die of shock, and the operation should be limited to as small an area and done as quickly as possible. In regard to localization I have found useful in the dorsal region Horsley's old rule of 10 cm. above the superior line of anesthesia, however slight the anesthesia may be. We seldom find in spinal cord tumors the profound anesthesia we find in transverse lesions from other causation, and consequently I take as my limiting line the slightest blunting of anesthesia. I think also that we should not refuse this operation simply because we are unable to decide whether the tumor is in the vertebræ or extradural or intradural, or even intramedullary. I know of no absolute means of deciding definitely on any one of these conditions. Thermo-anesthesia is no index. Over and over again, meningitis, tumors of the vertebra and tumors of the membranes have caused dissociation of anesthesia. I have seen many operations given up because the anesthesia was disassociated. I think it is a mistake. Even if exact localization can not be made I think the operation should be undertaken promptly and independently of the situation of the tumor with reference to the cord.

DR. MAX MAILHOUSE, New Haven: I want to endorse Dr. Bailey's statement with regard to the dissociation of sensation being due to spinal cord or spinal tumors. I recently had a case of recurrent carcinoma about and in the spine, which resulted in the spine forming a knuckle and pushing the cord to one side, in the middle cervical region, in which an early symptom was disassociation of sensation in addition to severe pain and marked spasm of the muscles, so intense that the case at first resembled a case of spondylitis; but one of the early symptoms, as I said before, was disassociation of sensation; and this disassociation, preservation of tactile sense, with diminution of pain and temperature sense, was very striking in this case.

DR. CHARLES W. HITCHCOCK, Detroit: I recall an interesting case which was presented to the Detroit Neurological Society last November by Drs. Inglis of Detroit and Klingmann of Ann Arbor, the findings of Dr. Inglis, who had seen the case, not being known to Dr. Klingmann. Dr. Klingmann accurately diagnosed the segments involved and the position of the tumor, and it was my good fortune to be present a week later at the operation performed by Dr. Max Ballin of Detroit. As in the case reported, too low a laminectomy was made in the hope of finding the tumor lower down, neglecting Chipault's rule of subtracting two from the determined segment, in the upper dorsal region, to find the exact spinal vertebra. The tumor was found just as Dr. Klingmann had diagnosed it, involving the sixth, seventh, and eighth dorsal segments. The tumor was removed, the patient did well, and the sensory and motor symptoms were both very much improved at the last report.

DR. M. ALLEN STARR, New York: My experience in spinal cord tumors is quite extensive, and I consider the diagnosis a comparatively easy one. I think that the typical symptoms appear so definite and distinct in these cases that there is hardly any danger of mistaking them for anything else. Early operation is essential and in two cases recently the question of whether the patients were syphilitic was decided by the Wassermann test. Finding the cerebrospinal fluid and blood absolutely negative, we avoided the supposed necessary delay of attempting to use mercury and iodid, as has been done so often. In my last case I first saw the patient on Saturday afternoon and the operation was done the following day. The tumor was found. The patient is recovering nicely and regaining power over and control of bladder and rectum that were absolutely lost when I saw her. The paraplegia is passing off. The excessive pain is, of course, the very most important symptom in these cases. I know of absolutely no condition resembling it in all respects except caries of the spine, and that, of course, can often be ruled out by physical examination, or certainly by an x-ray examination.

[13] Cushing, Harvey: Intradural Tumor of the Cervical Meninges, Ann. Surg., 1904, xxxix, 934.

[14] Williamson, R. T.: Diseases of the Spinal Cord, 1908.

The point is well taken by Dr. Bailey that the success in the operative interference with these tumors depends, first, on the avoidance of shock; secondly, the avoidance of hemorrhage; thirdly, the rapidity of the operation, and, fourthly, the limitation of the operation, so far as possible, to the essential parts. There is absolutely no necessity of making very large incisions in these cases. Horsley has laid down a reliable guide; it consists of measuring 4 inches above the level of the upper faintest trace of sensory disturbance, and by that I think the sensations should be tested always from below upward. I wish to make it very clear that a patient who is tested from above downward does not notice the little disturbance of sensation, a little loss, as you go down, but a patient with a disturbance of sensation if you get to the lower part and come up will immediately notice the improved sensation; 4 inches above the upper line you are pretty sure to find your tumor. Therefore, I think two laminæ are ample, the surgeon always having made his preparations to lay bare the lamina above if he fails to find the tumor under the two laminæ that are taken out. The tumor can not be taken out by simply dividing one lamina; two must be removed in order to give room for the enucleation of the tumor. So far as I have seen, these tumors have to be carefully elevated and enucleated in their removal. It seems to me that the prognosis in these operations is constantly becoming better.

Dr. Julius Grinker, Chicago: Much as we may dislike it, surgeons are still laboring under the antiquated idea that myelitis is largely syphilis of the cord, and not until they have subjected the patient to a course of rigorous antispecific treatment do they decide to operate. I believe that we should urge exploratory laminectomy in suitable cases, and that we should discourage the routine administration of antisyphilitic remedies, which are useless in spinal tumor and merely permit irreparable damage to be done to the cord structures, as in the case which I reported. I fully agree with Dr. Bailey that as few laminæ as possible should be removed, but certain exigencies will necessitate the removal of several laminæ. I think the danger from loss of support to the spinal column has been exaggerated. In my case four laminæ were removed, yet there is not the slightest sign of wakening in the spinal column.

THE ENDOMETRIUM AND SOME OF ITS VARIATIONS*

WILLIAM S. GARDNER, M.D.
AND
EMIL NOVAK, M.D.
BALTIMORE

It is surprising to note how few sharply defined and generally accepted facts have been crystallized out of the great amount of work which has been done on the histology and pathology of the endometrium. The numerous classifications of endometritis, for example, are ample evidence that none is entirely satisfactory, while some, as a matter of fact, are little short of absurd. Particularly unfortunate have been the attempts to classify endometritis along clinical lines, and it seems to have been decided that the most satisfactory or, at any rate, the least unsatisfactory basis for classification is a histologic one.

In this brief communication we propose first to present the results of our studies on the normal histology of the endometrium, with especial reference to the modifications thereof which are associated with the menstrual cycle. It is not our intention to take up a consideration of the various diseases of the endometrium, except in so far as our conception of these diseases may be influenced by our knowledge of normal variations in the structure of the uterine mucosa.

Our general study is based on the microscopic examination of the uterine mucosa from over 200 cases in the gynecologic clinic of the Baltimore City Hospital during the past three years. In the majority of these cases the mucosa was obtained by curetting, in a smaller number by extirpation of the uterus for one reason or another. In all cases the material was fixed immediately after removal, and the stain employed, with few exceptions, was the ordinary hematoxylin-eosin method.

In order to study the menstrual phenomena there was selected from the entire number of cases a series of 50 in which an accurate record of the menstrual history was available, including the date of the menstrual onset and usually of the termination of the period preceding the operation. In some of this group the material was obtained by routine curetting in connection with plastic operations of one form or another, there being no evidence of uterine disease. In other cases the mucosa was obtained from cases complicated by various associated conditions, such as myoma, salpingitis, displacement, etc., although no case was admitted to the series unless the regularity of the menstrual cycle was undisturbed.

In the main, therefore, the conditions surrounding our work have been similar to those under which was carried on the valuable work of Hitschmann and Adler,[1] to which we shall have frequent occasion to refer.

In order to appreciate the change which recent investigations have produced in our conception of the normal structure of the endometrium one need only read the descriptions contained in the various text-books of gynecology and anatomy. In the usually accepted sense the endometrium is the corporeal portion of the uterine mucosa, i. e., the portion above the level of the internal os. It is usually described as consisting of a surface epithelium, glands, and an interglandular tissue or stroma. The epithelium is of the ciliated columnar variety, differing from that in the cervix in that the cells are not so tall and slender, that the nuclei take on a paler stain and are situated near the center of the cells instead of near the basement membrane, and that the protoplasm takes on the eosin stain, while that in the cervix not [illegible] a pale hematoxylin stain on accoun [illegible] amount of mucus which it contains. The glands are described as being of the simple or branched tubular variety, being lined by epithelium continuous with and similar to that of the surface. The stroma, according to most authors, consists of a delicate reticular network of fibrillar connective tissue containing in its meshes large numbers of round, oval, or spindle-shaped cells. At the present time there is no unanimity of opinion as to the exact nature of the stromal tissue. Nagel[2] and Waldeyer[3] believe it to be of a lymphoid type and compared it to the stroma of the intestinal mucosa. Leopold[4] regarded it as a spread-out lymph gland (*Lymphdrüsenfläche*), while Johnstone[5] believes that it is of an adenoid type. Most of the best authorities, however, accept the view of Minot, that the stroma is merely a form of embryonic connective tissue, and this is probably the correct one.

From a physiologic standpoint the endometrium bears an important relation, whether active or passive, to the function of menstruation, and it would be interesting, if time permitted, to trace the various views which have at different times been held as to the changes which take place in the endometrium at the time of menstruation.

Unfortunately, up to recent years, the extent of these changes had been gauged largely by the comparative study of menstruating and non-menstruating uteri, and there had been no systematic effort to study the histologic structure of the endometrium from the beginning to the end of the menstrual cycle. Within the past few years, however, an important contribution to our knowledge of this subject has been made by Hitschmann and Adler,[1] whose work bids fair to revolutionize our former ideas of the histology and pathology of the endometrium. These observers, after a painstaking study of the uterine mucosa from fifty-eight women at various periods of the menstrual cycle, found that the endometrium, from the cessation of one menstrual flow to that of the next, presents a constantly-changing histologic picture. This cycle of changes they divide into four phases: postmenstrual, interval, premenstrual, and menstrual.

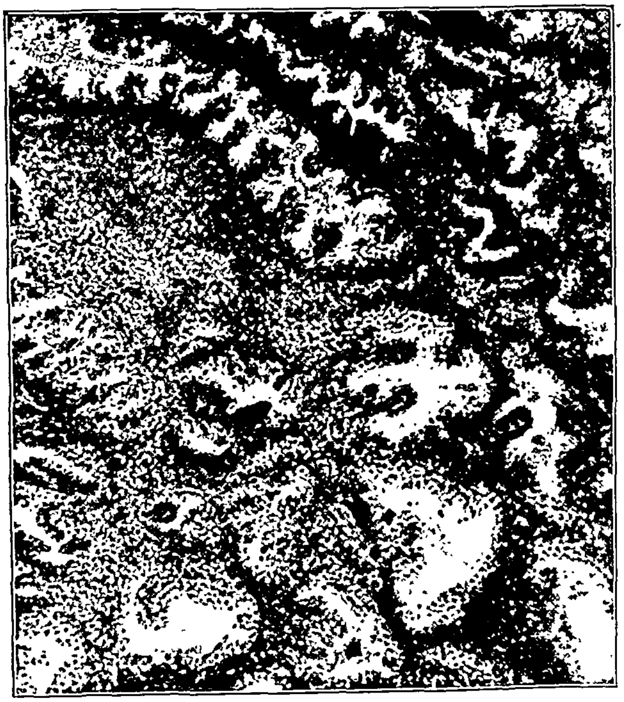

Fig. 1.—No. 749 (low power). Showing premenstrual gland changes. Note the increase in size and tortuosity and "saw-like" appearance of the glands. Curetting done one day before menstruation.

At the height of the menstrual flow the mucous membrane diminishes in thickness and the glands pour out their secretion, becoming narrow and straight. The surface epithelium is frequently lost, but this is not an invariable rule. After the period there takes place a very rapid cell growth in both the epithelium and connective tissue. The glands become larger and wider, although still quite narrow and straight. The epithelium is low and in a condition of rest. By about the fifteenth day the cell growth of the epithelium has progressed to such an extent that the glands become somewhat tortuous, and often assume a spiral or corkscrew-like appearance. Finally, six or seven days before the beginning of menstruation, the glands rapidly enlarge and become tortuous, the cells bulge into the lumen, the epithelium becomes higher and broader, and the lumen is filled with a mucous secretion. These gland changes are much more marked in the deeper portion of the mucosa than in the superficial, so that there is produced a well-marked differentiation into a superficial compact and a deep spongy layer. In this respect there is a marked similarity to the appearance of the young decidua, the resemblance being increased by the fact that the interglandular stromal cells in many cases assume an appearance very similar to or approaching that of decidual cells.

The important work of Hitschmann and Adler has attracted a great deal of attention, and already a number of articles, mostly confirmatory, have been published on the subject. From our own study of the fifty cases selected for this purpose we have been able to convince ourselves of the correctness, in the main, of the conclusions arrived at by Hitschmann and Adler. In our series of 50 cases we found that from a histologic standpoint 13 were to be classified as belonging to the premenstrual group. All of these 13 showed a marked increase in the size and tortuousness of the glands, some exhibiting a high degree of "papillary" formation, others presenting the less advanced saw-like appearance. In 10 of these cases the mucous membrane had been removed at short periods before the beginning of menstruation. In 5 cases the interval was one day (Figs. 1 and 2), and in the other 5 cases it was three, four (Fig. 3) six, seven and nine days respectively. The remaining 3 of the group of 13 cases which exhibited the so-called premenstrual glandular changes are especially interesting in that in all of them operation had been done at a period quite remote from the menstrual period. In one specimen (Gyn. Path. No. 262) the curetting had been performed eight days after menstruation and yet there were many hypertrophic glands throughout the section. As a whole the specimen was not absolutely typical of the premenstrual period, but in certain fields the appearance was quite characteristic. The other two specimens (Gyn. Path. No. 611 and Gyn. Path. No. 717, Figs. 4 and 5) were obtained eleven and ten days respectively after menstruation, and in both the glands presented very decided hypertrophic changes, Gyn. Path. No. 611 especially being typical in every

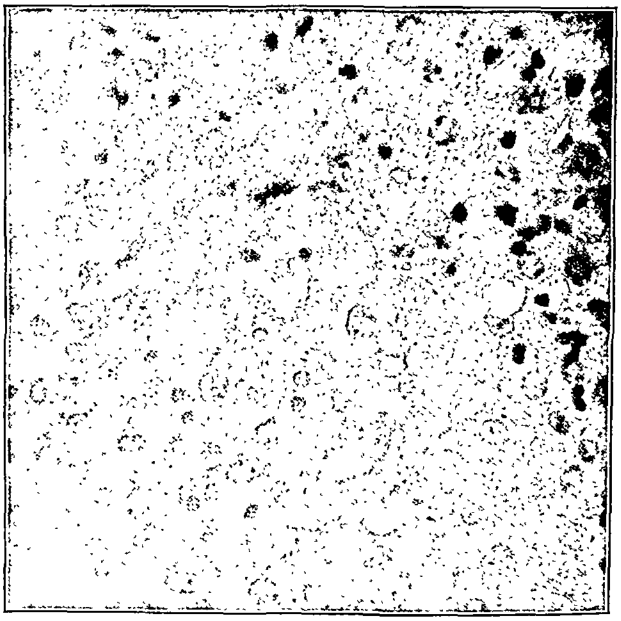

Fig. 2.—No. 57 (high power). Showing decidual transformation of the stromal cells. Curetting done one day before menstruation.

way. Of these three typical cases Gyn. Path. No. 262 was complicated by laceration and hypertrophy of the cervix, a moderate prolapse of the uterus and a small myoma. Gyn. Path. No. 611 was associated with a unilateral salpingitis and Gyn. Path. No. 717 with a laceration of both cervix and perineum.

The fact that premenstrual changes are found at a period so remote from the menstrual epoch, as in these cases, might perhaps be explained on the assumption of an individual peculiarity—as perhaps indicating an unusually early appearance of the glandular changes of the premenstrual period. This seems to us, however, as little more than an evasion of the question, and we feel that a simpler and more plausible explanation can be invoked. In view of the fact that the menstrual process, whatever its underlying cause may be, has as its most striking phenomenon the vascular changes in the reproductive organs, it is not unreasonable to assume that the constantly changing histologic picture in the endometrium is only a result of the influence of the increased blood suply on a very susceptible and readily-reacting tissue. The interesting experiments of Federn[6] and others have shown that the blood pressure of a woman reaches its maximum at the premenstrual period, the onset of menstruation being characterized by a rapid fall, after which the pressure rises gradually again to its high point at the next premenstrual period. The blood-pressure curve is therefore parallel with the histologic changes, and it is only natural to suppose that the latter may be largely influenced by the variations in the blood supply of the pelvic organs at different phases of the menstrual cycle. It seems logical to believe, however, that while the normal physiologic stimulus for the hypertrophy of the uterine glands is supplied by the hyperemia of the menstrual process, the artificial stimulus furnished by a pathologic hyperemia may also produce a greater or less degree of such change. The finding of marked hypertrophy of the uterine glands at other than the premenstrual period may thus be explained, although the factor of individual susceptibility must after all play an important part, for the occurrence of hypertrophied glands even in cases characterized by prolonged pelvic congestion is by no means constant.

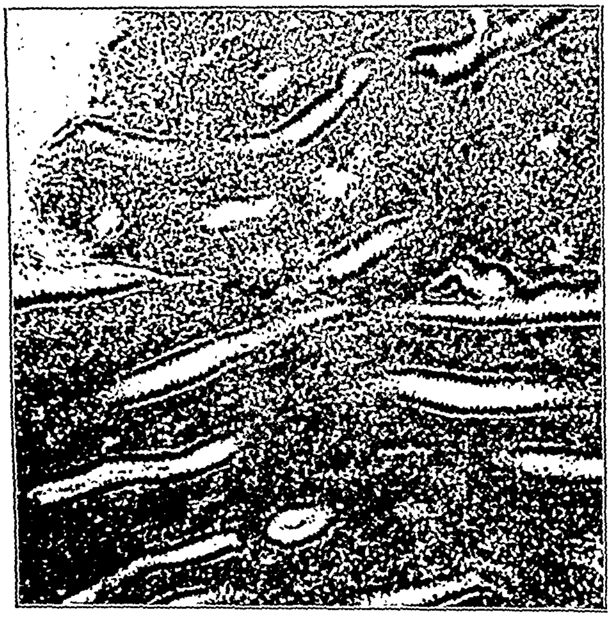

Fig. 3.—No. 647b (low power). Showing the straight collapsed glands of the post-menstrual period. Curetting done four days after menstruation.

Hartje[7] has recently employed the term "*subinvolutio mucosæ menstrualis*" to indicate the persistence of premenstrual glands for the first few days of the regeneration period. This, he suggests, may be due to a deficiency of the retrogressive changes normally occurring in endometrium after the onset of menstruation. We believe that he is correct in his opinion that the occurrence of the premenstrual picture in the period of from nine to fourteen days after menstruation is to be regarded as certainly pathologic.

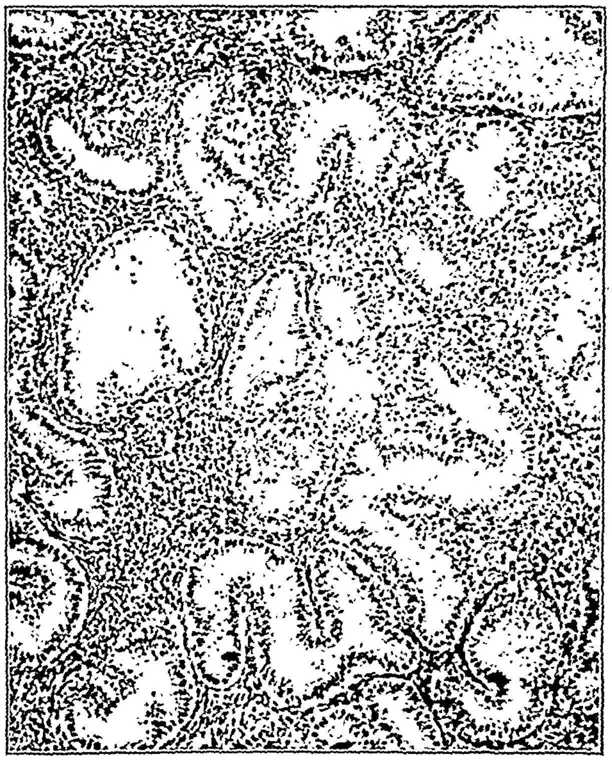

Fig. 4.—No. 611 (low power). Showing so-called premenstrual gland changes at a period eleven days after menstruation. Clinical condition, unilateral salpingitis.

Shickele,[8] in a recent article, also asserts that marked gland changes may occur without any relation to the menstrual process, as a result of uterine disease, adnexal affections, and displacements. In a rather large series of cases characterized clinically by bleeding (menorrhagia or metrorrhagia) in which it was difficult or impossible to determine the menstrual dates, we found marked glandular changes in a considerable number. Concerning this series we hope to report more fully at a later date. Kubo[9] likewise found gland hypertrophy, often very marked, in twelve of the ninety-nine cases of menorrhagia and metrorrhagia.

Whatever the explanation of the occurrence of gland changes under such circumstances may be, therefore, there seems to be no doubt that they may occur, and whether we characterize such changes as glandular hyperplasia or glandular endometritis, their pathologic nature should be recognized. The old rule of Gebhard, that the glands should be considered abnormally numerous if the distance between them is less than four or five times the diameter of the glands, is a very misleading one, for there are marked normal differences in different mucosæ in this respect. Moreover, in the examination of curettings, the microscopic appearance as to this point varies in different portions of the endometrium, and even more at different depths of the mucosa.

[9] Am. Jour. Obst., 1908, lvii, 675.

When one considers the individual variations in different women, with regard to the duration and amount of the menstrual flow, it is only natural that there should also be rather wide variations in the degree of gland change, exhibited at the premenstrual period.

As Hartje has pointed out, there is a gradual progression from the straight collapsed gland of the premenstrual period to the gland type of maximum differentiation—the gland with papillary outgrowths and secondary alveoli. In the most marked cases the glands of the deeper layer are markedly widened, the stroma is diminished so that the glands are almost in contact, and the epithelium is swollen with secretion. Many of the glands show well-marked papillary projections into the lumen, or in the less marked cases take on merely a saw-like appearance (*sägeförmige Drüsen*). Such glands as these were at one time considered pathognomonic of pregnancy (Opitz[10]), although the recent investigations of Hitschmann, Leitz,[11] Schwab[12] and others have shown clearly that this is not the case. The last named observer, for example, in an examination of a series of 41 curettings, found Opitz's "pregnancy" glands in 5 women, and, of these 5, only 1 was pregnant, the other 4, however, having a definite relation to the menstrual process—3 premenstrual and 1 menstrual. We have repeatedly seen such glands in the premenstrual mucous membranes of non-pregnant women. According to Hartje, the maximum gland changes, with papillary formation, etc., are seen in about one-third of the cases, the remainder showing merely the tooth-like or saw-like appearance characteristic of less advanced stages.

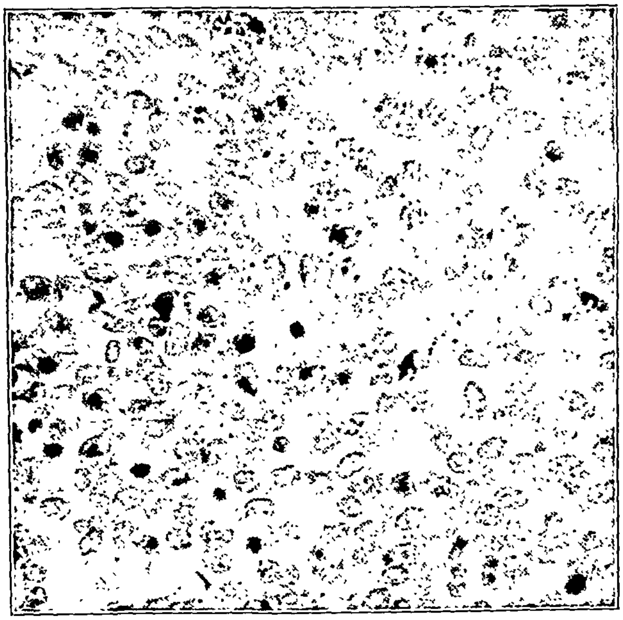

Fig. 5.—No. 717 (high power). Showing decidual transformation of cells at a period ten days after the menstrual period. Clinical condition, laceration of the cervix and subinvolution.

No less interesting than the gland changes of the menstrual cycle are those which take place in the interglandular substance or stroma. As already mentioned, Hitschmann and Adler found that in many cases the stromal cells assume an appearance so like that of decidual cells that there is no possibility of distinguishing them. When one considers that the decidual cell of pregnancy, according to the generally accepted opinion of the present day, is merely the overgrown stromal cell of the endometrium, such findings can scarcely be wondered at. It was Ruge (1880) who first stated that decidual cells may occur entirely independently of pregnancy, but it was not until recent years that the full significance of this view has come to be recognized.

In our series of 50 cases there were 4 in which the decidual modification of the stroma cells was sufficiently marked to be conspicuous. All of these occurred among the group of 13 cases in which the glands exhibited premenstrual changes. Among them, however, was one (Gyn. Path. No. 717), already alluded to, in which operation was done only ten days after menstruation, so that from this it would seem that other influences than normal menstruation may perhaps be capable of producing a decidual modification of the stromal cells.

A number of observers, notably Löfquist,[13] have found decidual cells present to a more or less marked degree independently of pregnancy, in association with such conditions as adnexal disease, tumors, displacements, etc. In most cases, unfortunately, the value of such observations is lessened by the failure of the authors to recognize the possible influence of menstruation in producing a decidual modification of the stromal cells. In a few of the recent reports, such as that of Goodall, however, this possibility seems to have been borne in mind, and it is quite probable that the stromal changes, as well as the gland changes, may be brought about by various conditions other than normal menstruation, such as inflammatory disease, displacements, tumors and tuberculosis. This would seem to be in keeping with the biologic law that the natural result of over-nutrition of tissue is overgrowth.

As in the decidua of pregnancy, the stromal changes of menstruation are seen most conspicuously in the superficial compact layer of the endometrium, these changes being just as characteristic of the premenstrual period as are the glandular phenomena already described. Like the latter, they reach their highest development just before the beginning of the menstrual p[illegible] to Hartje, the decidual-like cells ([illegible] *Zellen*) are seen in about one-third of the premenstrual cases. All stages of development are seen, from the normal stroma cell, which contains practically no protoplasm, to the typical decidual cell with its large oval nucleus surrounded by a well-marked protoplasmic area.

Even those who maintain that there is an essential difference between the decidua-like cells of menstruation and the true decidual cells of pregnancy have not been able to define wherein the difference lies. The conclusion is forced on us that the modified stroma cells of menstruation (*Uebergangzellen*) are simply different stages in a series in which the true decidual cell represents the maximum development. As Löfquist says, all the commonly observed changes in the endometrium may be regarded as the response of tissue to stimulation —as varying degrees of what has been called the "decidual reaction."

[10] Ztschr. f. Gynäk., xlviii.

[11] Ztschr. f. Gynäk., l.

[12] Ztschr. f. Gynäk., 1904, p. 1425.

[13] Zentralbl. f. Gynäk., 1901, xxi, 552.

Such observations as these throw a new light on the question of membranous dysmenorrhea. We have in our work observed two cases in which the membrane expelled from the uterus on microscopic examination showed the presence of characteristic decidual cells, even though, in the light of the clinical history, there was little or no possibility of pregnancy. Many similar cases have been recorded, and, with our knowledge of the extent of the menstrual phenomena in the endometrium, they are not so difficult to explain. Such cases are no doubt due to a throwing off of the superficial layers of the endometrium at the menstrual period, in a manner analogous to the expulsion of a true decidua. The exact cause and the mechanism of the process are still uncertain. The fact that dysmenorrhea membranacea is associated with an extensive shedding of the endometrium would not, however, seem to be a justification for the generalizing assertion advanced by some that such a loss of tissue is the rule in normal menstruation. The early writers, especially Kundrat,[14] believed that menstruation is attended with such extensive or even complete loss of mucosa, but the investigations of Gebhard and others seemed to demonstrate that, as a rule, there is very little loss of tissue during the process. More recently Hitschmann and Adler,[15] Ehrenfest,[16] and others have asserted that the views of Gebhard are not correct, and that there is often a considerable loss of substance during menstruation. The question, however, is still far from being definitely settled, and it is probable that there are marked individual variations in different cases.

The important bearing of this knowledge of the histologic changes corresponding to the various phases of the menstrual cycle can scarcely be overestimated. It at once places an interrogation mark after such terms as endometritis glandularis hypertrophica and endometritis glandularis hyperplastica, and deals a final blow to the early belief in the pathognomonic importance of the decidual cell in the diagnosis of pregnancy. While we are convinced of the correctness of the observations of Hitschmann and Adler on the changes which take place in connection with the menstrual cycle, we feel that their division of the cycle into phases is too schematic for ordinary use, and we do not believe that, as these writers assert, the changes characteristic of the various phases are so sharply defined that the time relation of the endometrium to the menstrual process can be determined from the microscopic picture "with accuracy and often to the day."

Finally, from the study of our own cases and from the reports of other authors, we believe that Hitschmann and Adler have taken an extreme view in practically asserting that glandular changes do not occur except in connection with the menstrual process. Both animal experimentation and clinical observation indicate that the actual underlying cause of menstruation is the secretory activity of the ovary, which produces an internal secretion or hormone essential for its occurrence. The principal effect of this substance seems to be of a vasomotor nature, and is exerted especially on the pelvic blood vessels. It is only natural to suppose that the endometrium plays a purely passive rôle in this phenomenon, and that the histologic changes observed in connection with menstruation represent merely the reaction of the endometrium to the process—a reaction which may, however, be elicited by other influences than that of normal menstruation.

6 West Preston Street—800 North Broadway.

ABSTRACT OF DISCUSSION

DR. HENRY O. MARCY, Boston: Twenty years ago I translated the works of Prof. G. B. Ercolain of Bologna, Italy, who commences his studies in the lower animals, showing that nature during the whole reproductive life is making ready for the continuation of the species. His work shows clearly from his standpoint that there is a process in every menstruation leaving a new mucous membrane with a new possibility of a reproduction of a new material for the development of the species, and that only in this way is impregnation possible. The placenta, in all animals, including the human species, consists of two distinct, fundamental parts, the fetal portion being vascular and absorbent, the maternal, glandular and secretory. In no case do the vessels of the mother anastomose with the vessels of the fetus. The transformation which the uterine mucous membrane undergoes during pregnancy produces the neoformation of a transitory glandular organ of secretion, constituting the material part of the placenta.

DR. JOHN G. CLARK, Philadelphia: It is gratifying to know that laboratory workers in America have taken up the interesting studies of Adler and Hitchens for verification or elaboration. Three years ago this section appointed a committee whose duty it was to offer a simplified nomenclature for endometritis. Great difficulty was encountered in arriving at conclusions, either from the clinical or histologic standpoint, for each writer was inclined to base his nomenclature on personal observations rather than on a uniform conception of this subject by the clinician and histologist. In the light of present investigations it is apparent that this failure in unanimity of opinion is due to the fact that the cyclic changes of the endometrium incident to the menstrual epoch were not then recognized. According to the investigations of Adler and Hitchens, which apparently Drs. Gardner and Novak have largely sustained, the tiny uterine glands, which are collapsed and almost straight immediately after menstruation, go through a definite evolutionary process, during which they increase in size, capacity, and histologic hypertrophy. In view of these cyclic changes it is evident that many of the discrepancies which have been noted by various histologists may be ascribed to the difference in the size and constituence of the glands during the twenty-eight day epoch. Many clinicians have looked askance at a histologic diagnosis, particularly when their clinical sense has been opposed to malignancy. I have always taken the ground that a careful clinical diagnosis is worth more than an inefficient histologic study, especially if the microscopist is not particularly skilled in this special line of pathology. I am sure that many uteri have been removed under the suspicion of malignancy in cases in which what was taken for hypertrophy of the glands or early malignancy was merely due to physiologic changes.

Clinically, therefore, I am sure that this most interesting study, which has been so well presented by Drs. Gardner and Novak, will have a very beneficial effect in the further histologic simplification of the changes in the endometrium. If the microscopist takes into account these changes, and if we, as clinicians, are careful to indicate to him the date of the operation as related to the last menstrual period, we will not lay him open to the error of sending back word to us that the glands are hypertrophied or suspicious of malignancy, when they are merely undergoing physiologic changes. The classification of endometritis will also be greatly simplified and placed on a more scientific basis by these careful studies.

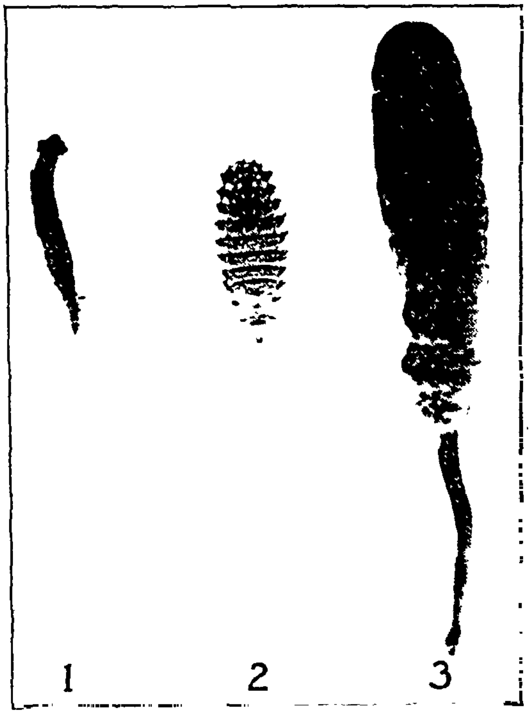
No Medicine Ads in Street Cars.—The New York City Car Advertising Company, which has control of advertising space in the New York City surface cars, has announced that no "patent medicine" or cure advertising will be accepted. This item is respectfully referred to those newspapers which continue to carry in their columns the advertisements of the "master specialists" and others of like ilk, which are manifestly calculated to deceive and defraud their readers.—*Bulletin of Illinois State Board of Health.*

MYIASIS INTESTINALIS DUE TO INFECTION WITH THREE SPECIES OF DIPTEROUS LARVÆ*

E. F. McCAMPBELL and H. J. CORPER
COLUMBUS, OHIO CHAMPAIGN, ILL.

Infections of man by the larvæ of dipterous insects (myiasis) are very infrequent, although such infections have been known to occur since the early history of medicine. Gilbert[1] reviews the history of infections of this kind in a recent article and calls attention to some of the earlier observations.

Myiasis occurs both within the body and on its external surfaces. Thus we have myiasis interna and myiasis externa. In the former should be included those cases in which the fly larvæ invade the dermis and subcutaneous tissues (myiasis hypodermatis) and those in which they invade the intestines (myiasis intestinalis). In the latter should be included those cases in which the larvæ invade wounds and open abrasions of the epidermis and dermis (myiasis dermatosis).



Larvæ isolated from case of myiasis intestinalis; (1) *Musca domestica*; (2) *Anthomyia canicularis*; (3) *Eristalis tenax*.

REPORT OF CASE

The case which we report is one of myiasis intestinalis from which three separate and distinct species of larvæ were isolated and is the only one in medical history, as far as we can determine, in which a mixed infection has occurred.[2]

History.—Mrs. McL., native of Ohio, resides on a farm, widow, mother of ten children. With the exception of two, all her children are deceased, some dying of infantile infections and two in later life of tuberculosis. The patient was in good health until the age of 57 (fifteen years ago), when she developed an acute catarrhal gastritis. The gastric trouble has since persisted. The patient has been under medical treatment almost continually since. At the age of 65 she began to pass "millions" of small green larvæ and a smaller number of white jointed larvæ which, the patient states, are similar to those recently passed. This attack of myiasis lasted about one year and the patient noticed nothing more of the larvæ until the age of 70 (two years ago), although there was no improvement in her health. She became very much emaciated during this period of five years. The larvæ have been intermittently passed in large numbers during the last two years and still persist. The patient noticed that during the last two years much larger organisms were passed in addition to those noted five years previous. She describes these organisms accurately and states that they are frequently twice the size of those which we have recently obtained. The patient states that she has had a continual feeling of distress in the abdomen since the attack of gastric trouble at the age of 65. The abdomen frequently becomes distended and colicky pains in the epigastrium have occurred at irregular periods. The larvæ, she states, are usually passed in a watery discharge and few, if any, have ever passed in the ordinary stools. Attacks of nausea and vomiting have occurred at irregular intervals since the gastric disturbances at the age of 65. She has never observed any of the larvæ in the vomit. The patient states that at the age of 65 her weight was 180 pounds. She does not associate the infection with the eating of any food and states that she always eats thoroughly cooked and fresh food. She states that the water which she has used has always been pure well-water. The surroundings of the home of the patient show nothing more insanitary than is usually noted about the average farm. Manure piles and flies are abundant.

Present Condition.—The patient, aged 72, weight 90 pounds, is distinctly neurotic, anemic and much emaciated. The abdomen is slightly distended and tender on deep pressure. The patient states that there is a constant ache throughout the abdomen. The pain seems to be partially localized in the epigastrium. Occasional colicky pains occur. The patient is constipated and does not have intestinal passages unless induced by cathartics. For this purpose she has used Epsom salts almost exclusively. At irregular intervals she passes large numbers of larvæ (250 to 500 c.c. fluid containing as many larvæ as possible). The larvæ are not passed in the usual stools but in a watery discharge. The patient states that a great amount of abdominal pain precedes the passage of the larvæ. Cathartics and aperients have failed to eliminate the larvæ from the intestines. Examination of the circulatory system shows a well-marked mitral lesion and rather advanced arteriosclerosis. The respiratory system is negative except for a slight nervous dyspnea; respirations, 25; pulse, 90. Genito-urinary system and urine are negative. The patient is easily nauseated and frequently vomits. She is confined to her bed the greater part of the time and is quite weak. The appetite is absent and the diet almost entirely liquid. Well-marked mental abberrations in regard to the activity of the larvæ within the intestines are noted.

Parasites.—The larvæ which we have examined, some of which were still alive, were passed three days previous to the time we obtained them. They proved to be those of the following species of dipteræ: *Anthomyia canicularis*, the small black flower- or house-fly; *Musca domestica*, the common house-fly; *Eristalis tenax*, the drone or flower-fly.

As myiasis has been noted due to each of these species they will be briefly considered.

THE INFECTING ORGANISMS

Anthomyia canicularis.—This is the common small black house-fly or flower-fly. The family of flies to which this species belongs *(Anthomiidæ)* is composed of a large number of species and the larvæ feed almost universally on decomposing vegetable matter, growing plants, and some few species on the eggs of the grasshopper and locust. In Europe *Anthomyia canicularis* has been noted frequenting vaults and is often spoken of as the "privy-fly." The larvæ are elongated in shape, composed of ten segments and measure 1 to 1.5 cm. in length. They are rounded posteriorly and narrow

[2] For the opportunity of study and subsequent diagnosis of this case we are indebted to Drs. V. B. Weller and W. F. White.

toward the anterior end. Each segment possesses a pair of lateral branchiæ, which are used for respiration while the larvæ are in fluid media. Each segment possesses also a pair of prolegs. This species of larvæ were the most prevalent of any passed in the case which we report.

The larvæ of *Anthomyia canicularis* have been reported as parasitic in man probably more often than any other of the dipterous insects. They have been noted to occur in the intestines, ear, vagina, and female urethra. A review of the literature shows about thirty cases of infection with anthomiide larvæ. In about twenty-five cases of these the intestines were infected. Of the total number of cases reported five were in the United States. It is impossible to state just how many of the cases were due to *Anthomyia canicularis,* as frequently the exact species was not determined. It seems that there are about twenty authentic cases of myiasis due to this particular species.

Musca domestica.—This is the common house-fly. The eggs (120 to 150) are deposited in horse-manure almost exclusively, but also occasionally on other excreta and decomposing vegetable matter. After the hatching of the eggs, which occurs in from six to eight hours, the larvæ feed on the decomposing animal and vegetable material. The larvæ are white pointed maggots 1 to 2 cm. in length and composed of nine or ten well-defined segments. Around each segment are a number of short branchiæ, which serve as respiratory organs. The larvæ grow rapidly, molt twice, and reach full size in from four to five days. The pupæ which follow persist for four or five days and from these the adult fly emerges, making a total of eight to ten days for the entire cycle. These flies are thought to pass the winter in the pupal stage.

Comparatively few larvæ of this species have been passed in the case reported. Cases of myiasis with the larvæ of this species are rare, there being only five or six authentic cases in the literature. Some of the other members of the family *Muscidæ* frequently infect wounds, ulcers, the nasal sinuses, ear and occasionally the intestine.

Eristalis tenax.—This is the so-called drone-fly. It is somewhat larger than the honey-bee and shows a marked protective mimicry for this last-named insect. It is a flower-fly and very active. It belongs to the family *Syrphidæ,* of which there are 2,500 species, 300 having been described in the United States. This fly is occasionally observed within doors in the late autumn. The larvæ are famous for their "rat-tailed" appearance. They are found on decomposing animal and vegetable matter and in soft mud. The larvæ measure 2.5 to 3 cm. in length and consist of seven segments, each bearing a pair of tubercles or prolegs. A well-defined head and mouth parts are absent. The anterior end possesses two pairs of hooklets. A long slender projection 2 to 3 cm. in length extends from the posterior portion of the body and this contains a small, contractile tube with breathing pores at the end. This appendage is projected up and is used by the larvæ to obtain air when buried or in fluid media. At times the larvæ are quite active and crawl about.

Cases of myiasis with *Eristalis tenax* larvæ are extremely rare. No cases are recorded in which accurate data are given. It is the rarest of the three species considered in this report.

GENERAL CONSIDERATIONS

The source of the infection in this case of myiasis intestinalis can not be definitely determined. The patient possibly ate the eggs or newly hatched larvæ with food materials. It is not probable that adult larvæ were ingested without the patient's knowledge and we do not think from the examination of the patient that the larvæ or eggs were purposely ingested. Finlaysen's[3] suggestion that the eggs which may be deposited around the anus and the larvæ, after the hatching of the eggs in from six to eight hours, invade the intestine from this source, is credible. We are of the opinion that there has been only one, with a possibility of two, infections in this case. We think that the primary infection occurred seven years ago when the larvæ were first observed. If there was a second infection it must have occurred two years ago at the time the occurrence of the large number of the larvæ was noted. We do not know but that larvæ may have been passed during the interval. At the time the larvæ were first noted and since there has been gastric trouble. This is a common observation in cases of myiasis. The cases are too rare to assume that the patient has been continually reinfected.

In reviewing the literature from an entomological standpoint we were surprised to note that comparatively nothing has been done in the study of the metamorphosis of the various insects. The bluebottle fly (*Calliphora erythrocephala*) is practically the only species which has been studied.

The following facts may be noted in regard to flies: Some lay no eggs, living larvæ issuing from the female (viviparous). It has also been noted that when certain of the dipteræ become parasitic no wings are developed. Nothing seems to be known as to whether the larvæ may reproduce, as has been noted in the embryonic types of some other low forms of animal life. The sexual organs in the larvæ, according to most entomologists, are not completely developed until after the adult fly stage is reached. The larva is entirely different from the adult fly and during the pupal stage which intervenes all the organs of the larva, except the reproductive, undergo degeneration and are regenerated. Such an arrangement suggests a very high specialization of these organs and it may be possible that when these larvæ become parasitic within the body reproduction may take place. It seems positive that the eggs can hatch and the larvæ grow to full size in the intestine of man. It has also been observed that larvæ may exist for very long periods of time within the body.

There seems to be four possible explanations for the continued presence of the larvæ within the body.

1. Persistence of the larval state for two to seven years. It must be assumed that very large numbers of eggs or very young larvæ were ingested, bearing in mind the number which have been passed. There is one case in the literature of twelve years standing.

2. The reproduction of the larvæ within the intestine. This would most easily account for the large numbers passed for a series of years.

3. The completion of the cycle by the hatching of the larvæ into the adult parasitic fly (wingless) and the laying of eggs by these flies in the intestines. We have observed no adult flies or remnants in the excrement.

4. The continued reinfection by the eating of eggs or larvæ or the deposition of eggs around the anus and their subsequent invasion of the intestine. There is the possibility that this patient was infected twice, once seven years ago and again two years ago. There is also the possibility in this case that the patient purposely ingests the larvæ. We think that this possibility has been excluded.

---

[3] Finlaysen: Brit. Med. Journal, 1889, i, 1285.

Of the four possibilities we are inclined to believe that the first, with possibly the second, furnish the most logical explanation for this interesting case of myiasis.

Experiments will be made and reported on later as to the effect of the various digestive enzymes on the larvæ and their activity.

PREVENTION OF MALARIA *

SEALE HARRIS, M.D.

Professor of Practice of Medicine and Clinical Medicine in the Medical Department of the University of Alabama; Visiting Physician, City Hospital

MOBILE, ALA.

Statistics show that malaria prevails in every state in the union except Wyoming; but because of climatic, meteoric and geologic conditions favorable to the growth of the anopheles mosquitoes, the southern states and the states adjacent to the Mississippi, Missouri and Ohio rivers show the greatest mortality from the disease.

Statistics compiled from the last census[1] show that there died, from malaria, in the United States in the year 1900, 14,909 persons, distributed by states as follows:

Alabama	1,055	Montana	5
Arizona	17	Nebraska	32
Arkansas	1,730	Nevada	10
California	119	New Hampshire	18
Colorado	21	New Jersey	110
Connecticut	110	New Mexico	89
Delaware	19	New York	308
Dist. of Columbia	63	North Carolina	527
Florida	366	North Dakota	4
Georgia	1,011	Ohio	156
Idaho	4	Oklahoma	134
Illinois	497	Oregon	23
Indiana	340	Pennsylvania	140
Iowa	84	Rhode Island	24
Kansas	261	South Carolina	749
Kentucky	344	Tennessee	987
Louisiana	1,030	Texas	1,331
Maine	16	Utah	6
Maryland	131	Vermont	9
Massachusetts	70	Virginia	409
Michigan	168	Washington	13
Minnesota	9	West Virginia	34
Mississippi	983	Wisconsin	5
Missouri	965	Wyoming	0

Of those who died from malaria in 1900, 9,320 were white and 5,589 colored. In the last census the colored population was approximately one-ninth of the whole, while more than one-third of the deaths from malaria were among the negroes. This high death rate from malaria among the negroes, who were formerly supposed to be more or less immune to the disease, may be accounted for by the fact that the negro population, in the states showing a high death rate from malaria, is large, and the negroes, representing the laboring and poorer classes, live in insanitary surroundings and, either from poverty or neglect, do not take treatment for the disease.

I have seen anopheles mosquitoes breeding in Central Park in New York; I have seen the plasmodium of malaria in blood obtained from the child of a millionaire residing on Fifth Avenue, and it is the same variety of mosquitoes, and the same type of protozöon, that I have seen in the swamps of the rural districts of the far south.

The problem of malaria, since it affects all sections of our country and all races and classes of our citizens, is a national one, and I shall discuss it from that point of view, though I admit that the section of country which I represent is vitally interested in this subject. In this connection I submit a few paragraphs from my address[2] as chairman of the section on medicine of the Southern Medical Association, delivered in Atlanta last November.

> Perhaps the most important health problem which affects the prosperity of the south is malaria. One has but to travel in the eastern, northern and western states to find that in those sections the south is regarded as a hotbed for malaria. No doubt thousands of settlers have sought homes in the west and elsewhere in preference to the south, because they feared to take their families to a section which they considered so unhealthful. Many travellers avoid the south, and capitalists have been deterred from making investments in our section because of the fear of malaria. I realize that such impressions are largely due to prejudice and to ignorance of the health conditions of the south, but it is also true that we have more malaria than we should have because, with our present knowledge of the disease, it should soon be stamped out of our towns and cities and made a rare disease in the country. . . .
>
> I have not statistics to show how much malaria has decreased in the south in the past two or three decades, except in the state of Maryland,[3] but its prevalence has been wonderfully lessened and it has become a much milder disease, so that to-day the severe types are rarely seen.
>
> The south is enjoying splendid prosperity in all lines, and she should erase from her fair name the blot of malaria, because it is a disease which can be prevented, and which interferes very materially with her industrial development.

Malaria destroys more lives every year than have all the epidemics of yellow fever in the past half-century, and there are several millions of our citizens in the United States to-day whose wage-earning capacity is limited because of the mild and chronic forms of the disease; yet malaria is preventable, and quinin is a specific for the disease.

In my opinion, malaria is a much more serious disease than yellow fever for the reason that one attack does not confer immunity, as in yellow fever, but predisposes to subsequent attacks; and because malaria is considered such a mild disease it is not properly treated and often assumes a chronic form which saps the vitality of the individual, thereby rendering him more susceptible to all other diseases, which are made more serious by the complication of malaria. The effects of yellow fever are soon over, while the victim of malaria may have the disease for years. I believe that the high death rate from nephritis in the southern states may be largely accounted for by chronic malaria.[4]

The existence of a few cases of yellow fever in a city causes a panic which destroys its commerce; there is an exodus of a large portion of its population, and cities, states and the nation will spend thousands of dollars in quarantines and in stamping out the disease; yet in the same city there may be thousands of cases of malaria —nothing is thought of that—and there has never been any organized effort to stamp out malaria because its ravages are "seen so oft" and we are so "familiar with the monster's face" that we endure it as if conditions could not be remedied.

[4] Marchiafava and Bignami: In Twentieth Century Practice of Medicine, New York, 1900, William Wood and Company.

Both malaria and yellow fever are transmitted by mosquitoes, the only difference being that they are carried by different varieties of mosquitoes which breed under different conditions: the anopheles breeding in puddles, undrained ditches, swamps, and in the scum on the surface of stagnant and slowly moving water along the banks of rivers and small streams, while the *Stegomyia calopus* has its habitat in the standing water of old cans, bottles, gutters of houses, badly drained sewers and other water-containers in and around human habitations. The anopheles must be infected by biting a malarial subject just as the stegomyia must get the infection from man. Since the above facts regarding the transmission of yellow fever and malaria are true, it would seem that the same measures should be employed in stamping out malaria as were used so effectively in stamping out yellow fever in Havana and in the Canal Zone. According to Colonel Gorgas,[5] the mosquito crusade in Havana not only freed that city from yellow fever for the first time in more than a century, but practically eradicated malaria at the same time. The number of deaths per year from malaria, in the city of Havana, before American occupation, averaged 350; after three years of sanitation by Colonel Gorgas and his assistants the deaths were reduced to 40 per annum.

That malaria may affect the welfare and destiny of nations is shown by the fact that students of history believe the decadence and downfall of ancient Greece and Rome was, to a great extent, due to the life-and-energy-sapping disease—malaria.[6] They believe that malaria is largely responsible for the transformation of the most learned, cultured and physically the strongest race of people in the history of the world into the ignorant and morally and physically degenerate people who to-day live among the ruins of Greece, which is now regarded as a "death hole for malaria."[7] The writings of nearly all the Roman authors contain many references to severe and destructive epidemics of malaria, and the efforts to drain the deadly Campagna date back before the time of the Cæsars. The prevalence of malaria in Italy no doubt had much to do with breaking the spirit of the ancient lordly Roman, "who was greater than a king," and thus helped to bring about the decline and downfall of the Roman empire.[8]

In the earliest years of this republic, and even in the first few decades of the last century, malaria was prevalent in the southern states to an extent which greatly interfered with their development. At that time quinin was such a rare and expensive drug that it could not be obtained, particularly in the rural districts, and nothing was known as to the nature and cause of the disease, so that thousands died from the malignant types of malaria.

The first capital of Alabama, St. Stephens, which, at one time, in 1810, was a thriving town of several thousand people, was literally wiped off the earth because malaria was so prevalent and of such severe type that its inhabitants either died or abandoned their homes. With our present knowledge of malaria, the inhabitants of old St. Stephens could live in perfect health, without one of them having a symptom of the disease which a century ago destroyed their prosperous little city.

Malaria was the principal obstacle to the completion of the Panama Canal by the French; and I may add that it has been the cause of the failure of many smaller enterprises in our own land.

Now let us consider the question of how malaria affects the prosperity and happiness of our nation to-day. I will first discuss the question of what malaria costs the United States, of how much money is spent each year because of the ravages of this now mild and easily preventable disease.

According to the census for 1900, there died from malaria in the United States 14,909 persons, and, estimating the value of a human life at $3,000 (the legal estimate is $5,000), malaria costs our nation from loss of life alone $54,727,000 each year. The death rate from malaria is very low; probably not one out of 500 people affected dies from the disease, and, adding to the death losses the loss of time and decreased earning capacity of the millions in the United States who are afflicted with the chronic and mild types of the disease, and the money paid out by the people in quinin and other medicines, to say nothing of the doctors' bills, on account of malaria, the cost of malaria to our country is enormous and astounding.

Dr. Albert Woldert, of Tyler, Texas, in a paper[9] read before the Texas State Medical Association, gives statistics from the hospitals of the United States Army posts in Texas in the year 1901, showing that one person in seven residing in those posts had malaria at some time during the year; and, according to his statistics from the railway hospitals, located in all sections of Texas, one railroad employé out of every four had malaria. Dr. Woldert states that about 3,000 people die annually from malaria in Texas, and he estimates that the financial loss from malaria to the people of the State of Texas during the year 1901 amounted to the enormous sum of $5,333,320. If it cost Texas that sum, the loss to the United States is at least $50,000,000 to $100,000,000 per annum. These figures give what malaria costs in cold cash, and do not take into account the sorrow and suffering of the millions who are afflicted with this preventable disease.

Is it worth while to combat, and to hope to exterminate, a disease so widely prevalent in the United States?

In answer to this, I would point to what has been accomplished by the Italians in the last five years. Though Italy has suffered more from malaria than any other nation, it should be said to the credit of her physicians that they have studied the disease most carefully and have contributed more than those of any other nation to our present scientific and practical knowledge of malaria. The Italian Society for the Study of Malaria has made most valuable contributions to the science and literature of the disease. The Italians have also made practical use of their knowledge of malaria by aiding the physicians in their campaign against the disease, and even though in financial difficulties Italy has spent millions of dollars to prevent the disease. She not only enacted and enforced laws to stamp out malaria, but went into the manufacture of quinin, selling it to her citizens at the cost of production and giving it free to her poor. That this expenditure of money and the campaign against malaria as made by the Italian government and its physicians was wise is shown by the result. The mortality rate from malaria in Italy for the past five years has been reduced two-thirds (Thayer). Think of the saving of lives and suffering to the people of our country if our mortality and morbidity rates from malaria can be reduced even two-thirds!

[6] Jones, Ross and Ellett: Malaria: A Neglected Factor in the History of Greece and Rome, 1907, Cambridge.

[7] Ross, R.: Malaria in Greece, Jour. Trop. Med., 1906, ix, 341, 351.

[8] Jones, W. H. S.: Malaria and History. Ann. Trop. Med. and Parasit., 1907, i, 529-546.

[9] Woldert, A.: Malarial Fever, Its Expense to the *People of Texas*, Transactions of the Medical Association of Texas, 1904, pp. 37-61.

The results in the mosquito crusades in Havana and in the Canal Zone should encourage us. As I have said, malaria was practically exterminated in Havana, and the following extract from Gorgas' last report[10] shows how malaria is being conquered in the Canal Zone under the most favorable circumstances:

> In 1906 we had from malaria 233 deaths; in 1907, 154 deaths; and in 1908, 73 deaths. That is, with a force more than one-third larger in 1908 we had from malaria less than one-third the deaths that we had in 1906. I consider malaria the best measure of the sanitary work done. In 1906, out of every 1,000 employés we admitted to our hospital, from malaria, 821; in 1907, 424; and in 1902, 282. That is, we now have only about one-third the amount of malaria among our employés as we had three years ago.

President Taft, in a recent address, said: "The sanitation of the Canal Zone has made possible the completion of the Panama Canal, the greatest enterprise in the history of the world."

Colonel Gorgas, in an address before the Academy of Medicine in New York, said: "With the removal of yellow fever, malaria and other tropical diseases, the tropics will become the centers of civilization of the world." If it is possible to eradicate those diseases from the tropics—and medical science has practically eliminated yellow fever from the diseases to be considered—how much simpler and easier will the problem be in the United States! It seems almost as feasible to stamp out malaria as yellow fever, and I believe that, with our present knowledge of the disease, it will soon become one of our rare diseases and that it will not be many years before our public health authorities will quarantine against malaria as we do now against yellow fever.

In discussing methods for the prevention of malaria, it may be well first to state the precautions to be used with an infected individual, which are largely the same as with a case of yellow fever, i. e., he should be (a) isolated (placed under a mosquito-net or in a screened room) to prevent his infecting anopheles mosquitoes; (b) the mosquitoes in the house should be destroyed by burning sulphur or pyrethrum; (c) the persons in the house or others exposed to the bites of infected mosquitoes should have preventive doses of quinin (3 grains, morning and night); (d) after the patient has been relieved of all symptoms he should take six grains of quinin a day for a period of at least three months, to be certain that he can not infect the anopheles mosquitoes in his community (Thayer).

Malaria should be classed as a reportable disease. Physicians should be required to report to the city and county health officers the name and location of each patient suffering from malaria, just as is now done with yellow fever and typhoid; and, as in those diseases, the source of infection should be searched for and removed if possible.

To protect the inhabitants of a community, whether in the city or in the country, efforts should be made to destroy all anopheles mosquitoes. Every accumulation of stagnant water, whether large or small, which can become a breeding-place for mosquitoes, should be drained or filled in, or oiled, when those measures are not practicable. The débris, green moss, and decaying vegetable matter on the surface of the water along the banks of slowly running streams should be removed because that is a favorite place for the breeding of anopheles mosquitoes.

When it is not possible to destroy all mosquitoes in any community, every person should sleep in screened rooms, or under mosquito-nets, from early spring until the mosquitoes are destroyed by the frosts of winter.

In badly infected communities (malarial localities) every person should take prophylactic doses of quinin during the summer and autumn months.

A physician in performing his daily duties can do great good by treating each malarial patient as if he had any other infectious or contagious disease, and by instructing his patrons as to the mosquito origin of malaria. He should inform his patients that malaria is infectious and of the methods to be employed in preventing its spread.

There should also be carried on a systematic campaign of education among all classes of people, by means of lectures and by widely distributed tracts, written in popular style, regarding the mosquito transmission of malaria and of how the disease may be prevented, because without the cooperation of the public a crusade against any disease can accomplish but little.

There should be organized a national association for the study and prevention of malaria, just as was done in Italy, with auxiliary state and county societies in the sections most infected.

The medical societies and boards of health in each town, city, county and state affected should take up the work of stamping out malaria. The American Medical Association, and particularly the Section on Preventive Medicine and Public Health, should aid in this great work, at least, by lending its influence toward a practical solution of this problem.

The United States Public Health and Marine-Hospital Service should also be called on to assist in stamping out a disease which causes so many deaths and so much suffering. Malaria is of more importance to the welfare of our country than yellow fever, and the scope of the United States Public Health and Marine-Hospital Service should be enlarged and its force increased so that a trained body of sanitarians can be employed in the fight against malaria just as has been done in epidemics of yellow fever. Malaria may be at times an interstate disease and already the health officer of Mobile is protesting against the introduction into that city of severe cases of malaria from the tropics.

Congress should be urged to create a special commission for the study and prevention of malaria, and to provide an appropriation sufficient to carry on the work. It seems to me that, at this time, a separate commission could accomplish more than by placing the work in the hands of any of the departments of the government now existing, because such a commission could be composed of physicians of wide influence in the localities most affected, men who would be especially interested in getting results and men who could enlist the active cooperation of the various county and state boards of health. The physicians composing such a commission should have hospital facilities for the study of the disease, because there are many problems connected with malaria which have not been worked out.

Congress has appropriated money for the study and prevention of yellow fever. Malaria is a similar disease, and, in my opinion, is of greater importance, certainly, at this time, to the welfare of the entire nation, than yellow fever ever will be again. Congress appropriated $50,000 for the study and prevention of the boll weevil and also considerable money for destroying parasites in wheat and corn; it has given large sums for stamping out diseases in cattle; why should it not be called on to aid in stamping out a distinctly preventable disease, which destroys thousands of human lives and decreases the earning capacity of many hundreds of thousands of American citizens?

---

[10] Gorgas, W. C.: Annual Report of the Department of Sanitation of the Isthmian Canal Commission for the Year 1908. Government Printing Office, Washington.

The problem of the prevention of malaria means much to the southern states and, therefore, much to the nation. If our section can be freed from malaria, the poor whites and negroes will be stronger physically and, therefore, better laborers; our naturally fertile lands will become more productive; the cotton mills will come to our cotton fields because of our cheap and efficient labor; our iron and other mineral resources will be developed to an extent hitherto not dreamed of, and our Gulf and Atlantic cities will become shipping and manufacturing centers of great importance. If we can [illegible] that malaria, like yellow fever, can be forever stamped out of the south, our prosperity will amaze the world.

ABSTRACT OF DISCUSSION

Dr. Marshall Langton Price, Baltimore: There is one subject on which I think I ought to dwell, especially because of its importance; that is, the actual value of the statistics of malarial fever. I doubt very much, under present conditions, that 80 per cent. of the deaths which are actually recorded from malaria in the United States are due to any infection from the malarial parasite: I believe this, from my experience in Maryland, in which state there are probably recorded annually from 8 to 10 deaths from malaria. This makes an impressive showing in figures; but when the original certificates are examined one finds about as follows: returned as the primary cause of deaths, malaria, 2 weeks; intestinal perforation and peritonitis, 10 days. Analyze the death statistics of any state and similar conditions will be found. Outside of the extreme southern states there are not more than 100 deaths from malaria during the year, in the states north of Tennessee. Of over 400 deaths reported in Illinois, I doubt very much if 20 were due to malaria. During the Spanish-American War some observer made a tour of the military camps. He found from 50 to 100 men in each camp laid up with malaria and being dosed with quinin. He was told: "They have malaria." He reached some regimental surgeon, who, I am sorry to say, for the sake of Americans, had a very strong German accent. The observer asked: "How many cases of malaria have you?" He said: "Not one, sir!" His patients were not being dosed with quinin; they were being treated on rational grounds for typhoid fever. In Maryland one of the best studies of typhoid fever was that made by Thayer and Hewittson in 1893. At that time malaria was endemic around the suburban portions of Baltimore. Those cases were not founded on conjecture, but the actual parasite was found in the blood. Since then malaria has almost disappeared from Maryland and in every 1,500 to 2,000 cases of supposed malaria the malarial parasite is found in about 5, as determined by the examination of fresh blood or smears. I have no doubt that in the South, as Dr. Harris states, malaria is a very common disease; but I do not think we ought to accept the usual diagnosis by the physician as an actual basis for malarial figures. I think we ought to reject all such cases and base statistics entirely on those cases in which the parasite is demonstrated in the blood either by staining or by an examination of the fresh specimens.

Dr. Henry B. Hemenway, Evanston, Ill.: Illinois is exceedingly defective in vital statistics, the state administration having paid very little attention thereto. It is estimated by the Illinois State Board of Health that 80 per cent. of the deaths that occur in Illinois are reported. Of course, that would increase the 400 deaths from malaria quite materially —put it up to 500; but it has been my observation, as Dr. Price has said, that a large majority of the diagnoses that we get as malarial fever would, with the blood test, prove to be typhoid. So far as I know, in Cook county there have not been more than five cases that have shown the peculiar organism of malaria, within perhaps a couple of years. Some were found along the Desplaines River some time ago. Most of the cases that are recorded as malaria—as fatal cases of malaria, particularly—are really typhoid; and that is one reason why the study of malaria can hardly be separated from the study of typhoid, and the study and prevention of yellow fever. I am glad that attention has been called to the necessity of including among the reportable diseases malaria as much as smallpox or scarlet fever.

Dr. W. Forrest Dutton, Walker's Mills, Pa.: Dr. Price brought up a point that I would like to hear explained, not at any length, but satisfactorily enough for those present, namely: mixed infection. I would ask Dr. Harris to give us, if he can, the frequency of typhomalarial infection, the percentage of cases in which it occurs. I do not think there is any reason why we should be at loss to differentiate typhoid from malaria except when there is a mixed infection. I think that by means of microscopic examination of the blood smears we ought to be able to make our diagnosis very readily.

Dr. Juan Guiteras, Havana, Cuba: I do not think that in the tropics a mistake in diagnosis is frequently made between typhoid and malaria. I understand the mistake may be made with filaria, hookworm and tuberculosis, but not with typhoid fever. The cases reported as malaria in the tropics—in Cuba at least—would seldom be found to be cases of typhoid fever. Of course, the mistake is possible, but it is exceptional. The unfortunate term of typhomalaria that was invented some time ago was in vogue at that time, because we had no definite means of diagnosing typhoid fever. Malaria in Cuba has fallen from the third and fourth place on the mortuary records to the tenth place. Malaria was originally placed by us on the list of reportable diseases because of the yellow fever campaign. Another important factor in bringing about this reduction of the malarial fevers in Cuba is the isolation of the sick at the port of entry. We are detaining a very large proportion of the patients with malaria who formerly went into the country and, of course, became propagators of the disease. The majority of patients with malarial infection coming from Central America, Mexico, the Mississippi delta, etc., are found with fever on the inspection made by the quarantine officer and are sent to Las Animas Hospital; once there, they are not discharged until they are cured.

Dr. J. N. Hurty, Indianapolis: I believe thoroughly in education as the best, perhaps the only way to get these subjects before the people. Sometimes, however, I become discouraged. I went before the county board of health of a certain county in Indiana where malaria was reported as existing to a considerable degree, and from which county several deaths had been reported, and presented the reason of malaria. This county board of health was composed of the county board of commissioners. So I presented the whole matter as carried by mosquitoes and I thought I had made a very excellent impression on the board—that it would take action, print circulars, and perhaps go to draining, and encouraging drainage in the county there and get rid of stagnant water; and I was very confident that I had educated these "practical business men," as they called themselves. One of them turned around and with his hand combed a couple of handfuls of manure out of his beard, saying: "Young fellow, you don't believe all of that stuff, do you?" So sometimes education does not educate, and especially with the man who considers himself highly practical, and—worse yet—with the man who has made a semifinancial success. I think that those men are so consumed with conceit that one cannot get at them. We had a legislator who had cunning enough to amass a hundred thousand dollars. He has decided to be a practical man in his neighborhood; and so practical and so eminent was he in the state that the governor appointed him on a very important examination committee; and when he heard one of our lecturers say that consumption was rarely, if ever, hereditary, he said he did not care if "a thousand doctors and thousand doctor books said that it was not hereditary" he knew that it was. Now, you see, we have a certain class of people (I suppose they exist in other states), who cannot be educated.

Dr. Seneca Egbert, Philadelphia: I remember distinctly that somewhat more than fifteen years ago the secretary of one of the southern states, speaking of the importance of artesian water as replacing that from shallow wells, declared in one of the bulletins that because of the improvement in the well-water supply in certain parts of his state the reduction in malaria had been over 50 per cent. We all know now that the malaria of which he wrote was not malaria, but must have been something else. My experience was that a great many of the people in a locality where I was working used water from very shallow wells; and I remember in one case water that was undoubtedly contaminated, in this village, was taken from wells located a very short distance from a stream, and everybody believed that the wells filled from the stream. On the higher ground above the wells there were twenty-three privy vaults and pig-sties draining directly toward these wells en route to the stream. These people were persistently ill every season, with so-called typhomalarial fever. I doubt very much if any one in the neighborhood had a true case of typhoid fever, but I am convinced that they were suffering from filth infection, and that their general health was depressed by that absorption of human and pig filth. So it seems to me that possibly we may explain much of the reported typhoid fever or malaria if we dubbed it simply filth infection, and occasionally, paratyphoid.

Lieut.-Col. Jefferson R. Kean, U. S. Army: With reference to the statement of Dr. Guiteras that there were about 40 deaths from malaria in the City of Havana during the past year, I think that the showing is even better than that, my recollection being that it was only 8. Although the difference between 40 and a lower figure is not great for a city of 300,000 inhabitants in the tropics, I wish to call attention to it as an evidence of the thoroughness of the work being done in Cuba. It means the practical extermination of the pathogenic varieties of mosquitoes in and about Havana. The last year that I was in charge of sanitary affairs in Cuba we had to send away from Havana to get anopheles larvæ to show to our inspectors as a part of their course of instruction. I regard Havana at present as not capable of infection with yellow fever and if any one visits the city, unless he stays much longer than most American visitors, he will probably not see a single stegomyia mosquito. In so excellent a paper it seems ungracious to criticize small points, but there is one which I would like to see corrected. I do not want to detract at all from the excellent public work for the extinction of malaria that is being done by the Italians and which we would do well to imitate; and this notwithstanding the fact (as Dr. Price will probably bear me out) that many of the local epidemics which appear in the northern states are initiated by Italian laborers who bring in the infection. While giving the Italians all due credit for their work I do not like to hear them credited with that of men of other nationalities. Laveran, who discovered the malarial organism, was a French army surgeon, and it was a British army surgeon, Ronald Ross, who first demonstrated the agency of the anopheles mosquito in conveying malaria.

Dr. Liston H. Montgomery, Chicago: I do not think very much of the term typhomalarial fever. Has the Italian government succeeded in reducing the number of deaths by two-thirds?

Dr. Seale Harris, Mobile, Ala.: Yes.

Dr. Montgomery: It shows that in Italy governmental control is paramount; furthermore, Cuba has succeeded in stamping out yellow fever, and practically malaria also. Cuba has a national department of health; and those two examples would, it seems to me, go to show that our government should have a national department of health, with its physician in the cabinet, as has been done in Cuba. Not only this, but such government commission should have supervision over other contagious diseases, such as tuberculosis and bubonic plague, the latter of which is liable to come from South America, particularly Venezuela, and get into New Orleans almost any day.

Dr. J. H. White, New Orleans: The national government is standing guard at this present moment.

Dr. Marshall Langton Price, Baltimore: Those of us who have been in New Orleans are familiar with the magnitude of Dr. White's work in the last yellow fever epidemic. I think the problems that he tackled were among the most difficult undertaken in this country; and the brilliant results all of you know.

Dr. J. H. White, New Orleans, La.: When I undertook the work of sanitation against yellow fever in 1905 we were confronted with 196 square miles of territory in the City of New Orleans, whereof 44 square miles are built up rather closely; 660 cases of yellow fever; control more or less lost; and nothing but the indomitable pluck of that magnificent people could have enabled success. It was a question of extermination of all mosquitoes in the City of New Orleans or failure. We put 3,000,000 pounds of salt in the gutters in order to make sure that there were no mosquitoes breeding there. Six weeks afterward the water in the bayous through which the gutters reach the lake showed 5 per cent. saline. We cleaned the whole town from end to end; we oiled 68,000 cisterns, and every rain barrel that we could get our hands on; we left nothing to breed on in that 44 square miles of territory; and in the latter end of September, 1905, a new-born baby could have been placed in the streets of New Orleans to sleep. The extinction of yellow fever was not the only result. A result as truly gratifying was that estivoautumnal malaria which had been common in New Orleans, was distinctly cut down. Having a hospital under my supervision, it is only in the past six months that we have begun again to get estivoautumnal malaria by the river front, by reimportation both of the mosquito and infection from the tropics, proof of this being as follows: At certain points on the river we have lying in close contact steamers from Tampico, Coatzacoalcos, and London and other British ports. These Englishmen occasionally develop estivoautumnalis when they have not been in the tropics for a year or two, and after lying for two weeks in the port alongside the wharf close to the Tampico or Coatzacoalcos ship, and to the collection of water caused by the railroads digging out dirt to fill up their embankments: thus proving the reinfecting of our mosquitoes which have come back only in the last two or three years to that point.

Now, as to governmental control, New Orleans has done her duty very well indeed, in the matter of malarial fever. As I recollect it, the annual death rate in New Orleans back as far as the '70's from fever supposed to be malarial, and probably malarial (because typhoid infection was very uncommon), was close to 335 as the average; and to-day, I think it will not go to 25; and that is municipal work: it has nothing to do with the nation. As a national representative, I say that I think this a pretty good showing in New Orleans, which, if you paralleled with Havana, Dr. Guiteras and Dr. Kean will admit, is a far harder proposition; New Orleans is extended on a mud-flat, below the level of the Mississippi half the year round, the water so sluggish in its flow that it has to be pumped out mechanically, and there is every possible inducement to the mosquito to make its habitat in and around New Orleans. Gradually, slowly but surely, they are eliminating the mosquito. A little more persistence, a little more care, possibly another scare, will be needed to bring them up to it; but I feel sure—as sure as a man can of anything that he has not seen done before him—that New Orleans will, in the next few years, be immune to yellow fever.

Dr. Seale Harris: What is the difference in death rate?

Dr. J. H. White: As I remember it, the general, as compared with the previous death rate, has been reduced about 2: among the white population, say from 19 to 17; among the negro population, a slight reduction, not so much.

Dr. G. Farrar Patton, New Orleans: Dr. White, with characteristic modesty, has not mentioned what was really the greatest victory that he won there; that is, overcoming the prejudice of the people. I think it is safe to say that at the outset ninety-nine out of every hundred people in New Orleans believed that the mosquito doctrine was all nonsense, and before the campaign was half over the people of the city, down to the street arabs, were convinced of its absolute truth. That was accomplished mainly by a "hammer and tongs" campaign of education, attended with positive proof in the way of results. As Dr. White jokingly says, he preached in every church in New Orleans, and it is true: he preached a gospel that saved the lives of the people more effectively, perhaps, than the preachers who ordinarily occupied those pulpits save the souls of their people and I consider that this victory—the moral and intellectual victory—transcended in magnitude the wonderful success achieved in banishing the disease proper before the coming of frost.

DR. R. A. NEALE, Chicago: About thirty years ago I was physician to the poor of Washington, D. C.; I had assigned to my territory a section of the city that was nearly surrounded by water, and it was called "Foggy Bottom;" the three thousand odd people living there for ten or twelve years had been suffering intensely from ague; the little huts that they built were nearly all covered with shrubbery and vines. Foggy Bottom was a piece of land that was marshy; in a number of years it became filled in and houses were built there. My predecessor showed me an average every summer of over 600 cases of typical malaria in that Foggy Bottom. I did not know anything about Italy's great progress in preventing malaria, but I was fearfully annoyed every night by the numerous mosquitoes flying about my head, and I decided that I must get rid of them. I made all of those people get rid of all vines and shrubbery, cut down every tree, and put screens in all the windows and burn sulphur in their rooms. I had them makes hundreds of bonfires at night, hundreds of them; because the breezes would come at night and blow the mosquitoes away down the river; in the morning it would come the other way and blow them back again. The next year of my term, instead of having 600 cases of malaria I had only 50; the third year there were only 25, and nearly all of the patients had recently come to reside in Foggy Bottom.

DR. SEALE HARRIS, Mobile, Ala.: I expected my statistics to be questioned, but those obtained from the United States Census Reports are the only ones available. I am willing to admit that many deaths reported as malaria are due to typhoid fever, tuberculosis, sepsis, hookworm and other diseases, but it is a remarkable fact that along the Mississippi Valley, along the valleys adjacent to the Missouri and Ohio rivers, and in the South, where conditions are favorable to the development of anopheles mosquitoes, there are so many "ignorant" physicians who report these cases of malaria. The United States Army surgeons, I believe, represent as good a class of physicians as we have, and the statistics from the United States Army posts, which are located in all sections of Texas, show that one person out of every seven residing in those posts had malaria in 1901. Not only that, other statistics compiled by Dr. Waldren show that in the railroad hospitals in Texas, which are located in cities in different parts of the state, where it is certainly probable that there are competent physicians in charge, one patient out of every four has malaria. I admit that my statistics may not be correct, but from my own observations in the South I believe that there a large proportion of the population has malaria at some time during the year. The death rate from malaria is low, and is growing less, and it is a very mild disease, yet it does affect the vitality of the individual; it makes him more susceptible to other diseases, and I believe it materially affects the general mortality rate. I am sure that malaria is growing less prevalent in the cities where there is proper sewerage. I believe that will account for much of the decrease of malaria in Maryland. In Havana and the Canal Zone where the sanitation was worked out largely against mosquitoes the general mortality rate was reduced about 50 per cent., and as Dr. White has pointed out, the general death rate has been reduced in New Orleans since the crusade against mosquitoes.

Regarding the amount of typhomalaria in the South, I do not know of any cases in which typhoid and malaria have been found at the same time in the same individual, but it is certainly true that in the convalescence of typhoid fever malaria does occur. In the tropics during the Spanish-American War, when a large number of United States soldiers had yellow fever, they suffered a great deal more from the malaria that followed. I realize the difficulties of educating the public, but the lessened prevalence of malaria in the South is due to the fact that the educated, "well-to-do" people have their homes screened with the idea of preventing malaria by keeping out mosquitoes, and with such people malaria is less prevalent than formerly. Another reason why malaria is less prevalent in the South is the widespread use of quinin. Dr. H. F. Harris, of Atlanta, studied a large number of cases of continued fever and the greater majority of them responded to the Widal test for typhoid.

I desire to thank Dr. White for calling attention to my mistake as to Laveran being an Italian, but the Italians have done a great deal in studying malaria, and the literature published by the Italian Society for the Study of Malaria is greater in volume than that contributed by any other country.

My object in bringing this paper before this Section is this: While malaria is not perhaps so severe an infection as yellow fever, typhoid fever, tuberculosis and many other diseases, it is one of the more prevalent diseases in the United States. There is a great opportunity for sanitarians in the South to make records by decreasing the death rate from malaria, and in doing that it would be one of the greatest things for our country, particularly for the South, because we have the reputation of being unhealthful. Eliminate malaria and you will certainly decrease the general death rate.

SOME MINOR GYNECOLOGIC MATTERS OFTEN OVERLOOKED*

I. S. STONE, M.D.
WASHINGTON, D. C.

In routine practice we may fail to appreciate certain rare or obscure diseases which are very annoying to our patients, although not dangerous to life. We find a number of cervical erosions, classified as infectious, which are due to other causes. There are numerous infections of glands of the genital tract which are not understood, and which are not successfully treated because the seat of the infection is not exposed and thoroughly sterilized. Many patients have numerous deep vulvar glands, especially about the vestibule, which may become veritable nests for gonococci or other microbes and will perpetuate an infectious discharge indefinitely unless opened widely and sterilized by iodin or some equally good application. Skene's glands in the urethra are known to harbor infectious organisms and to cause a persistent urethritis. This disease requires surgical treatment if a cure is obtained. The glands must be opened up, thoroughly exposed and treated. My purpose at present is to direct attention to certain nerve changes about the genital tract.

NEURITIS AND HYPERESTHESIA OF THE VULVA AND VAGINA

This is a frequent and often unsuspected cause of annoying symptoms. One of the commonest mistakes made by physicians who treat gynecologic patients is to call every sensitive surface an inflammation. Careful discrimination will enable one to detect certain nerve alterations and to see the difference between them and vaginitis or vulvitis, due to infection or persistent irritation of any kind.

These nerve changes are often seen in a consulting practice. The patient has had fairly good, and perhaps rather active, treatment for infectious disease and has not obtained relief. In fact, nearly every patient coming under observation has been subjected to much local treatment, all of which has probably done harm unless such treatment finally results in a diagnosis.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

SYMPTOMS

The patient is usually a neurasthenic or a neurotic. She is usually suffering from associated disease, which is often due to impaired function rather than to organic mischief. She has a leucorrhea due to more or less endocervicitis, and believes that the discharge causes the painful condition of the vagina. The parts are extremely tender, are often red, and occasionally swollen. Micturition is generally painful in those cases with red and swollen mucosa. The disease is not confined to any special class. We encounter it in virgins relatively as often as in married women. The patient is often told by some physician that she has "ulceration" of some portion of the vaginal mucosa. A slight erosion of the cervix becomes the *point de résistance* of much medical treatment, and in a recent case the patient told me that she had "three different ulcers of the cervix cured by treatment, only to have them return as before."

It is a common practice of many physicians to rely strictly on local treatment for a cure of this disease, because they fail to see the real cause back of the local manifestation. Obviously, all applications of tampons, iodin, ichthyol, boric acid, and glycerin fail unless they benefit by entertaining the patient while time and improved general health bring about a cure. It is in this class that we see the evil result of suggestion. Many of these patients are acutely sensitive to wrong impressions and they are easily and often inadvertently led to think that a slight displacement of the uterus or an enlarged ovary, or possibly some slight intestinal irritation, if treated perhaps surgically, can be cured. It is well known that the uterus has often been removed because the supposed irritating discharge could not be otherwise cured. Of course, in certain cases the neuritis may not easily be relieved or the symptoms even palliated. I have seen several cases associated with urethral caruncle, and I am inclined to believe the pain of a caruncle is always due to an associated neuritis. We have all seen caruncles removed without relief to the patient, and unless they are associated with cystitis the failure is generally due to nerve changes.

DIAGNOSIS

If methods of examination were more exact we would find fewer cases of acute infectious disease of the vulva and vagina and relatively numerous cases of neuritis or hyperesthesia. Naturally, we resort to well-known methods of treatment rather than make the effort to establish a correct diagnosis based on careful investigation. Such empirical practice will perhaps long retain a hold on our favorable consideration, although we always have at hand perfectly satisfactory, even if slower, methods of reaching a diagnosis and consequently a proper indication of treatment. We fail to see any improvement in the teaching or treatment of the minor gynecologic cases since the days of Sims, Emmet and Thomas, and hence surgery has become far more prominent in this specialty than before, and I am confident more than is desirable or necessary.

It is impossible for every one at first to distinguish between cases of hyperesthesia and those of neuritis, but it is comparatively easy for those accustomed to make such distinctions in other portions of the body. Without resort to electrical or other scientific measures, the usual observation and care which is exercised by any physician who is on the alert for these cases will enable him to detect the condition under discussion. In any event, a diagnosis between hyperesthesia and neuritis is not absolutely necessary. The precise portion of the vulva or vagina which may be the seat of the disease is altogether uncertain. I find that the sensitive area in by far the greater number of cases is about the vestibule and introitus. Recently a case of neuritis was seen with dark discoloration of labia around the glands of Bartholin, due to repeated cauterizations, probably with silver nitrate. Occasionally I find a sensitive spot or area on or near the cervix, as in a case recently seen in a pregnant woman. This latter was, however, associated with marked neurotic symptoms which closely resembled inflammatory mischief.

ILLUSTRATIVE CASES

CASE 1.—Patient referred by Dr. C.

Miss X., aged 35, had been treated for infectious endometritis by curettement and intrauterine cauterization, without relief. She had swelling and edema of the vulva with each menstruation, causing great distress. When first seen there was redness; slight swelling and some erosion of the vulva with painful micturition and occasional itching. The urine was nearly normal and contained no sugar. She had been examined for eczema by a competent dermatologist who recognized the unusual features of the case. This patient had associated neuritis and endometritis. I made the diagnosis and treatment was carried on by her family physician, who reports a gradual improvement and nearly perfect restoration to health.

CASE 2.—Patient referred by Dr. W.

Miss Z., a thin, nervous virgin, aged 27, with hymen intact, had been told that she had "ulcers" on the vulva. She had a very slight leucorrhea, but I failed to discover the ulcers or even redness about the vulva or vagina. The uterus was small and retroverted, otherwise all the organs were normal. Her complaint of painful and sensitive vulva and vagina led me to go slowly in reaching a diagnosis. Examination of the discharge was negative, there being no possible infection of the vagina. She passed out of my hands and an abdominal operation was performed for a slight displacement of the small uterus, with the result that she believes herself benefited, although the time has been too short for definite results. Of course, the lesions found at the operation did not explain the symptoms and the girl will finally recover when her nervous disease disappears either by good fortune or by proper treatment.

TREATMENT

The suggestions already made indicate the line of treatment to be adopted. The diagnosis made, the treatment becomes a matter of simple attention to the general health of the patient. In irritable and sensitive vaginæ we should avoid all irritating applications and should use either drying powders or emollients. It should be remembered that any fluid may cause burning and smarting if a neuritis be present. The indication is to protect the tender surfaces so far as lies in our power.

Stoneleigh Court.

ABSTRACT OF DISCUSSION

DR. ROBERT MORRIS, New York City: The colon bacillus is not infrequently an infecting agent in the vagina and uterus. At present I am having some investigations made in a number of cases in which the discharge from the endometrium is secretional in character. This discharge forms a culture medium for the colon bacillus, and the colon bacillus may extend its field from the vagina to even the peritoneum. Another point which I wish to make is in connection with a minor gynecological disturbance that is commonly overlooked, and to which I have given a good deal of attention during the past two or three years—the effect, the remote effect, of eyestrain, particularly in school girls. Recently I had two cases; one patient had an acute anteflexion; one had retrodisplacement. In both cases there was obstinate obstruction of the bowel to such a degree that both patients were in great distress, and there was a question whether or not they would be obliged to give up their school work. In both cases I was able to eliminate all factors except the eyestrain. The patients were sent to an ophthalmologist and both were well in thirty days. I am having a great deal to say on the subject of eyestrain, but not so much as the men who are throwing the subject into disrepute. A great many ophthalmologists have seen the horizon of this subject enlarged so enormously that they are speaking from imagination rather than facts. Let us speak from facts. In a certain proportion of minor gynecologic cases, particularly in young people, eyestrain is the cause and can be discovered by the proper ophthalmologist—who is not easily found. The ophthalmologist usually makes an examination with reference to an ordinary refraction and his report relates to the sight. That has nothing to do with the case. Remote disturbances are to be sought by men competent to do this. I said to an ophthalmologist recently, who had examined the eyes of a patient in which eyestrain was, in my opinion, the cause of the disturbance: "Now, have you examined with reference to muscle imbalance?" "No," he said, "I have just examined with reference to sight; I will take this matter up." There was a case that had slipped past an absolutely competent man who had not taken up this subject with reference to gynecologic features. It is a matter which has been overlooked by most of us, but let us send cases in which eyestrain is possibly the cause to the proper ophthalmologists, and let him give us either negative or positive testimony.

Dr. Mary E. Dunning, Newburg, N. Y.: I believe that nerve strain has much to do with many local conditions seen in our patients. A case worthy of note is that of a woman of 38, whose menstrual function had always been accompanied with terrific headaches and vomiting. Examination showed nothing abnormal in the pelvis excepting extreme tenderness of the adnexa, and there was a spur which blocked completely the left nares. Two pelvic hydroelectric treatments were given and the spur removed. She has had no nerve disturbances, menstruation has been normal and she has been perfectly well since.

Dr. Angeline Martine, Utica, N. Y.: Dr. Morris' mention of the colon bacillus being a cause of irritation in certain cases, reminds me of a case in a young unmarried woman of undoubted good reputation who had an irritation resembling grossly a gonorrheal infection. I had the discharge carefully examined under the microscope, and found that it was due to an infection by the *Proteus vulgaris*. I have had a series of seven or eight such cases which I have reported. The infection is very intense. One of the cases seems to have been contracted by the use of the public toilet. The source of the other cases could not be traced. The infection so closely resembles gonorrhea that much care should be observed in the examination.

Advantages and Disadvantages of Pasteurization.—One of the chief objections to pasteurization is that it promotes carelessness and discourages the efforts to produce clean milk. It is believed that the general adoption of pasteurization will set back improvements at the source of supply and encourage dirty habits. It will cause the farmers and those who handle the milk to believe that it is unnecessary to be quite so particular, as the dirt that gets into the milk is going to be cooked and made harmless. It is not proposed that pasteurization shall take the place of inspection and improvements in dairy methods. To insure the public a pure and safe milk supply should be regarded as one of the most important duties of the health officer. Whether pasteurization is adopted by a city for its general milk supply or not, no milk should be accepted that does not comply with certain reasonable chemical and bacteriological standards. This would aid the inspectors in enforcing good dairy methods. Pasteurization then must not be used as an excuse to bolster up milk unfit for home consumption. To insure this end, the health officer should have authority to condemn and destroy bad milk, whether or not pasteurization is practised.—M. J. Rosenau, in *Annals of Medical Practice.*

THE SANITARY REGENERATION OF SAN FRANCISCO

N. K. FOSTER, M.D.
SACRAMENTO, CAL.

Early in the morning of April 18, 1906, San Francisco was awakened by a severe shock of earthquake which, breaking the electric wires, set fires in many parts of the city. The same shock which set the fires destroyed the means of defense by breaking the water-mains, and the city was unprotected against the fury of the flames which raged uncontrolled for three days and nights. Few, if any, of the great fires of the world have equaled it in extent of property damage. Picture a city, rich, substantial, with a beauty and grandeur peculiar to itself, covering hills and valleys, with vast mercantile and manufacturing industries, changed in three days to a pile of broken brick and twisted girders, 2,560 acres of ruins, 28,188 houses destroyed, 275,000 people homeless, $350,000,000 property values wiped out of existence!

It was a time that tried men's souls; and never was American pluck put more fully to the test and never its superior quality more fully proved. There was hardly a person in the city who was not stricken to a greater or less degree; and thousands on thousands had not only the savings of a lifetime wiped out, but all immediate chance to work for a living destroyed. There was hardly food enough left in the city for a full meal for the inhabitants, most of whom were sleeping in the parks and vacant lots. The supply of water was very limited, and no fires were allowed in houses, so all cooking had to be done in the open air. The sewers were broken and clogged, the means of collecting garbage destroyed, and conditions were favorable for the spread of zymotic disease.

The conditions confronting the health authorities were serious but were fully appreciated, and long before the fire was out a complete organization was installed, composed of the medical service of the United States Army, the State Board of Health, and the City Health Department. The city was divided into districts, and over each was placed a local physician who was skilled as a leader as well as in his chosen work. He selected his own assistants from among the medical men of the city. Here let me give a word of tribute to the doctors of San Francisco. No class or profession was hurt so badly. Libraries, instruments, accounts and practice were all swept away and many of those fortunate enough to own their homes lost them also. Without price or any consideration they gave their time and skill not only to aid the sick and injured, but to save the city from a fate which seemed almost inevitable. The work they did was not spectacular, but its value to the city was none the less great and can never be properly appreciated. They went from house to house and camp to camp, inspecting, regulating, instructing, and, where it was necessary, backed by the strong arm of popular consent, enforcing sanitary measures. Connections with broken sewers were closed, water was boiled, body discharge buried, waste brought to sidewalks, and pollution of the surface of the ground forbidden. As a result of these measures there was practically no sickness in the city during the few weeks immediately succeeding the fire.

The people were largely living in the open air, eating simple, plain and wholesome food, and the waste matter was reasonably well destroyed. Business activities were at a standstill and personal attention was given to sanitary conditions. When, however, the reconstruction began and the sanitary inspection, which had been strict, was relaxed, typhoid and other zymotic diseases became prevalent and for several months the mortality and morbidity rates were above the normal, although at no time sufficient to cause alarm. Conditions, however, were favorable to the spread of disease and especially one like plague, which is carried by vermin. The sewers were broken and afforded an excellent means of communication for the rats from one part of the city to another. The ruins of the city gave ample hiding-place and the remains of lunches from thousands of workingmen gave sufficient food and excellent means for propagation.

The plague epidemic of 1900-1904 had been wiped out and for three years no case had developed, so when in May, 1907, one year after the fire, a case was found on the tug *Wizard* it was thought to be a fresh importation, and there is yet no certainty that it was not. No great uneasiness was felt until August, when it broke out with fury and soon appeared in many parts of the city. The exact source of this infection will never be known, but, no matter whether it was a lingering infection from the former outbreak or a fresh infection, the conditions were excellent for the spread. Thousands of refugees were living in tents and shacks built of any material that would give the slight protection needed from the weather. These habitations were without sanitary conveniences and were built close to the ground. The city was full of stables where the accumulated refuse gave a splendid home for vermin. Old board walks on streets and in back yards and rubbish in basements of undestroyed parts of the city was as common as in other cities. Slaughter-houses in the suburbs were pestilential holes. The sewers were broken and the garbage poorly collected. Rats were plentiful, and a widespread epidemic prevailed among them with nothing to keep them from a close contact with the people. With these conditions it is no wonder that those who had had to deal with the former epidemic of plague stood aghast at the prospect and trembled for the future, especially as plague cases were multiplying rapidly, for in September there were fifty-five cases in the city. It looked gloomy for San Francisco. The loss by the fire and the tremendous expense following it had almost broken the city treasury; and the losses in public buildings had left the state in little better condition; so that there was not the money necessary at the command of the health authorities to conduct the campaign the conditions demanded.

More than anything else was needed a man skilled in combating great epidemics and backed by a power that could make itself felt. Aid was asked of the United States Public Health and Marine-Hospital Service, and Dr. Rupert Blue of that service was assigned to the work. His experience with the former epidemic, when he had carefully studied the rat and its connection with the disease made him the logical man for the place, and his natural qualities as a leader and diplomat added materially to his qualifications. He began at once to arrange for a sanitary battle such as probably had never before been fought. For his executive officer he chose Past Assistant-Surgeon W. Colby Rucker of the same service, a man in every sense of the word capable, honest, enthusiastic, loyal and a thorough organizer. Together they constituted a force which inspired confidence in all with whom they came in contact and proved themselves a credit to their service. Both state and city authorities recognized Dr. Blue as the leader, gave him their hearty support and looked to him for results; and their confidence was not misplaced.

A campaign of general sanitation was laid out, the city divided into districts, each under an able leader, and daily reports made to headquarters. The work to be done was to make the city sanitary. To do this rats must be destroyed, their breeding-places broken up, their food-supply stopped; to use the expression of Dr. Blue it was necessary to "build them out." Ordinances were passed by the supervisors supporting this policy and orders were issued by the State Board of Health whenever it was possible to strengthen the hands of the department. The city was spending $30,000 per month besides the aid given by state and nation, but little progress seemed to be made. The cooperation of the people was needed; and it is to the credit of the organized medical profession of California that this was secured. In January a meeting was called by the Council of the State Medical Society, to which were invited a large number of business men. A few responded and became so impressed with the danger that a resolution was passed asking the mayor to appoint a Citizens' Health Committee of twenty-five. This he did and their work was of the greatest aid in saving the city. The whole city was awakened and soon every man employing help was calling his employés together and having them addressed on the subject of sanitation; and every one was made a committee to see that his own and neighbors' premises were clean. The women and women's clubs became active and efficient agents in the work; and in a short time the whole community was more deeply stirred in a move for better sanitary surroundings than any other large community had ever been.

While the enthusiasm among the people for better sanitary conditions was doing wonders in the way of cleaning up which could not have been accomplished by the organized health authorities for several hundred thousand dollars, it was evident that more systematic work must be done to restroy rats, and the Citizens' Health Committee promptly raised over $175,000, which was expended largely in the warfare on rats. Each household was required by law to have a closely covered metallic garbage-can, and the law was strictly enforced. Stables were made rat-proof, and only such persons acceptable to the officer in charge were allowed to move the manure out of the city—this to prevent the spread of infected rats and to force the rat-proofing of the stable, it being cheaper to do this than to dispose of the waste by other means. Old wooden sidewalks were torn up, shacks destroyed, piles of rubbish in basements and yards cleaned out, openings to broken sewers closed, and lumber piled so that cats could get beneath. In fact, all hiding-places and runways of the rodent were disturbed and his life made miserable and short with trap and poison. In fifteen months 350,837 of the rats were caught, besides the vast number dying of poison and never found.

In a few short months conditions had entirely changed and San Francisco stood forth the cleanest large city in the country; 1,025,977 premises had been inspected; 11,342 houses disinfected and 1,713 destroyed; 4,291,000 square feet of concrete basement and area floor had been laid, and 1,190,000 in stables; 3,967 stables had been concreted and 903 otherwise made rat-proof; 5,000 chicken-yards had been made rat-proof and 11,000 vacated; and it is estimated that 2,000,000 rats were slaughtered.

There were still many sores and scars from the recent burn, but as a rule they were well cared for and clean. The streets were littered with building material and in many places broken, but that is no measure of a city's sanitary condition. The streets and front yards may be clean, the houses bright with fresh paint, but the back yards and basements filthy. The front is no more a criterion of a city's cleanliness than is the outer garment of a person's. The condition of basements, stables and backyards, the use of garbage cans and proper collection of garbage, the absence of rubbish and the rat-proofing of buildings are the true measures of its cleanliness.

The plague has been a costly lesson to California, but she has smilingly paid the price and is profiting by it in a low death and morbidity rate. The spirit for better sanitation was not confined to San Francisco, but spread to other cities, and hardly one but bettered its condition; and the extent of betterment can be read by comparing the death rate of the year following with that of the year before. A campaign, the outgrowth of the one in the city, is still going on throughout the state in a way never before tried. A car with models illustrative of sanitary conditions, showing causes of disease and methods of avoiding, eradicating and curing, has been fitted up by the State Board of Health. The car was furnished free by the Southern Pacific Railroad Company and with its lecturers and attendants is being hauled free of charge by all the railroads of the state. This could hardly have been possible before the plague, but now it is gladly—yes, enthusiastically—done and the resulting good is beyond measure. We may have other cases of plague; situated, as we are, at the gateway through which so much immigration and business with the far East must come. It would be strange if we did not; but we know it, its cause and its means of spread and are on guard. We have fought the first great battle for the country and have won. The second may be on us, but it is just as likely to be on some of you on the Atlantic coast. It has spread with steady strides in a few short years to almost every country on earth and you are not far removed by water from some of its strongholds; it behooves you to take heed and learn from our experience and begin the fight before it is manifest. Dream not that you will catch the first case and check it then. Before you find human cases you will have a thoroughly infected rat population. Your only safety is in the extermination of that enemy of mankind.

This is not such a hopeless task as it may seem. If each householder will but look after his own premises and destroy breeding-places and feeding-ground the work is done. The value of a popular sentiment that requires that each person keep his holdings clean was strongly impressed on us. This sentiment needs, however, in the case of stress to be properly directed and in this a national department with its officers outside political machinations, trained to lead, educated for the work, with no other business interests to distract, is preeminently the best.

Paraplegia in the Aged.—Lhermitte discusses the cerebral, spinal cord or muscular origin of paraplegia in the aged and the disturbances in gait which result from mere functional incapacity. The latter depend mainly on the emotional reactions, the dread of the infirmities of age and the tendency to stay in bed on the slightest pretext. The idea of its being impossible to walk becomes more and more settled in the old man's mind, especially as his will power is growing constantly weaker. In bed he can move his muscles, but when standing seems to be unable to take a step. He can be encouraged to walk, leaning on a cane or attendant, and may cover miles with this aid, but gives up at once if deprived of this support. This form of paraplegia may be curable as the patient is reeducated to walk, and it should be eliminated before considering the organic forms. His article was published in the *Bull. de l'Internat, December*, 1908.

THE FRENCH GOVERNMENT TOBACCO FACTORY AT ISSY, NEAR PARIS

HYGIENIC NOTES *

FRANCIS DOWLING, M.D.
Foreign Member of the Société Française d'hygiène
CINCINNATI

While in Paris, France, during the summer of 1908, for the purpose of making some investigations in the department of hygiene, I received permission to visit the government tobacco factory at Issy les Moulineaux, near Paris.

I wanted to make some investigations in regard to the effects of tobacco on the eyes of the employés of the factory, along the line of similar investigation which I have made in the tobacco factories of America, but this permission was not granted; I was permitted, however, to examine into the sanitary condition of the establishment, and was afforded every opportunity in this direction by the courteous director of the factory. The following are some of my findings:

The large tobacco factory, situated at Issy les Moulineaux, a short distance beyond the fortifications of Paris, covers several acres of ground, and is about the largest factory of its kind in France. It employs 1,200 persons, of whom 1,000 are women and 200 are men. The structure is an immense one, built of stone and brick, and was finished in 1904, when the old establishment in Paris was removed to this location. It is up to date in all its appointments, has the latest modern machinery, and turns out only cigars, cigarettes, and tobacco for pipes. In the first division the machinery is all of French make. It turns out cigars and tobacco for pipes. There are some very ingenious machines there for compressing and packing tobacco into forty-gram packages (a little over an ounce). A machine will turn out 1,300 of these packages in an hour.

All the floors contain cuspidors with a disinfectant substance, and the rooms are kept scrupulously clean. In one room there is some American machinery that is made in London and Dresden. All the tobacco dust from the machines is conducted through pipes to a flue and escapes through a chimney in the roof, and in this way very little dust is to be found in the work-rooms, and there is comparatively little smell of tobacco. There are twelve large work-rooms in the establishment, each 40 meters long and 14 meters (about 130 by 45 feet) wide, with immense high ceilings. Besides these there are smaller work-rooms. The men are employed largely to do the heavy work, while most of the skilled work in turning out cigars and cigarettes is done by the women. The superintendent informed me that the women are more dextrous in the use of their fingers than the men, and hence are given the preference in this kind of work. I found some Cincinnati machinery in one of the rooms for turning out cigarettes. This room was called the American room.

Besides the rooms for French tobacco there is a large room devoted to American tobacco, labeled "Ohio," "Maryland," "Kentucky," etc. The colors of these grades of tobacco are about twelve in number. Each woman employed in packing the cigars in boxes has her number on the box, so that in case the boxes are not packed properly the superintendent can tell who is at fault. Most of the employés go home for dinner at noon; for those who remain there is a pantry and kitchen for warming their food. There is a library in the establishment, baths, an emergency hospital for those who may be injured, and a dispensary with a full supply of drugs for the factory doctor who visits the establishment daily. All the water used for drinking purposes is sterilized by machinery. There is a good-sized nursery (crèche) for the babies that the working women may bring with them, with a kitchen for preparing food, bath-tubs, closets for toilet, etc.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The majority of the women here were much more mature-looking in appearance than those I saw in the factories in America. I saw no very young girls, and, of course, no boys. Smoking is against the rules in the establishment. The women did not present the anemic appearance that one notices among those employed in our American tobacco factories. The men showed no symptoms of tobacco infection that I could discern; and the medical director says that tobacco amblyopia rarely occurs among them. They do not smoke to the extent that our American workmen do, and, then, the cigars are lighter, and a good many cigarettes are used instead of the heavy cigars that our people smoke.

The sanitary condition of this factory is as good as that of any that I have ever visited. There was no crowding in the rooms; there was plenty of breathing space, and the employés all looked healthy.

All the tobacco factories are government property, and they yield an enormous revenue. For the year 1907 the total number of employés in the tobacco manufactories of France was 15,171; of this number, 13,239 were females and 1,932 were males. There are twenty of these manufactories in France situated in the following cities: Bordeaux, Châteauroux, Dieppe, Havre, LeMans, Lille, Limoges, Lyons, Marseilles, Morlaix, Nancy, Nantes, Nice, Orleans, Pantin, Issy les Moulineaux, Reuilly, Riom, Tonneins and Toulouse. All the employés, both men and women, are eligible for retirement at the age of sixty-five, when they are pensioned by the government. By a law of March 22, 1905, the male employés are appointed from the soldiers who have served for at least four years under the French flag; consequently they are at least twenty-five years of age before they are employed in the factories. Foreigners are not employed in these factories; occasionally, however, exceptions are made, and foreigners are appointed; especially in the case of French women who marry foreigners, for the women thence by virtue of such marriages become foreigners, according to the French law. If they are employed before such marriages, they are retained in the factories under the classification of foreign employés. These marriages occur mostly at Nice, Toulouse, etc., the seaport towns of France. Women are not employed if they are beyond twenty-eight years of age, and practically the minimum age is eighteen years. That disgusting practice of chewing tobacco, too prevalent among our Americans, does not exist among Frenchmen.

A medical director who resides in Paris is at the head of the medical department of these tobacco factories, as well as the other factories of the state. There are local physicians attached to the various factories, whose duty it is to look after the hygienic condition of the institution, as well as to care for any of the employés who may be injured while on duty. These physicians are all under the supervision of the medical director at Paris.

As will be seen, there are no minors employed in these French tobacco factories. This is as it should be. They should also be excluded from our tobacco factories in America, and for this purpose we should have government supervision of our tobacco factories so as to have uniform laws enacted forbidding their employment. As it is now, each state makes its own laws governing the matter, and they are not uniform and very often they are not enforced. I know that in my city there are a large number of boys and girls employed in these factories, and I suppose it is the same in the tobacco factories of other cities. They are employed on the score of cheapness, as they command less wages than the adult. In my investigations made in our factories I found that nearly all of the boys employed there smoked to a greater or less extent. The environment of the factory seemed to stimulate this habit.

In the minor the use of tobacco in any form is highly injurious, interfering with the normal development of the mental powers, producing various nervous disturbances, especially nervous disturbances of the heart, as manifested by palpitation, weakness, irregular action, irritability and anginal pains.

The action of tobacco on the heart is well set forth in the Lettsomian Lecture by J. Mitchell Bruce:[1]

> In young men whose circulation is still structurally sound, the uncomplicated effects of tobacco, as presented clinically are palpitation in every instance; a sense of irregular action, poststernal oppression and pain in half the cases; and in one out of every eight either angina or uncomfortable sensations in the left arm; faintness or actual faints in one-third of the cases; giddiness and a feeling of impending death in a smaller proportion. As to physical signs, the heart proves of ordinary size in 50 per cent. of the cases, in a few slightly enlarged; the precordial impulse is very weak, but occasionally increased in force and frequently, and likely as not to be irregular; the pulse tension, with insignificant exceptions, is low. Of twenty patients, not one presented a cardiac murmur beyond a weak mitral systolic bruit, variable with posture and cubitus.

That the habitual use of the tobacco by the young causes stunting of the physical and mental growth is set forth in the observations of Seavers, of Yale University, who has for years studied the growth of students during their four years' time at the university. He observed that those who do not use tobacco increase in weight, height, chest girth and lung capacity more than those who do use it. He states that Hitchcock, of Amherst, has made like observations.

On those who are more advanced in life, from forty upward, tobacco seems to spend its force more particularly on the eyes, producing a gradual but progressive reduction of the visual power, together with a confounding of colors for central vision. Out of something like 3,000 cases examined by me, during a period of ten years, in the tobacco factories of Cincinnati, more or less disturbance was noticed in about 5 per cent. of the cases among the male employés who used tobacco to excess. The females were exempt.

The deleterious effects of tobacco on the system in general, or on the eyes, is due, as we all know, to the presence of a poisonous ingredient called nicotine. This oily, colorless fluid diffuses itself into the blood with as much rapidity as prussic acid, and a poisonous dose has been known to kill an adult in three minutes. Nicotine when heated to 250 degrees becomes volatilized and decomposed, but if watery vapor is present volatilization takes place without decomposition. When dry tobacco is smoked, the greater part of the nicotine is decomposed by the heat and passes off with the smoke. The more moist the tobacco—and the cheaper grades are usually damp—the more this is retarded. The cheaper grades of tobacco contain more nicotine than the more expensive ones, and consequently are more injurious to the consumers. The tobacco used for chewing purposes is usually very rich in nicotine. The action of nicotine on the blood is an interesting one; it first produces a temporary increase in the blood pressure; this is followed by a more prolonged reduction of the pressure, and this again is followed by an increase in the blood pressure (Tschirwinsky).

---

[1] Bruce, J. M.: Brit. Med. Jour., March 23, 1901.

On the blood corpuscles themselves nicotine exerts a marked influence. The red corpuscles become serrated in appearance, and when the drug is administered in large doses partial disintegration of the corpuscles takes place. In the experiment of Hare they are shown to arrange themselves in columns, instead of in rouleaux, in such a way that the edge of one corpuscle touches the edge of its neighbor. If the poison is added to the specimen under the microscope, the red corpuscles appear to disintegrate, and their diameter becomes smaller, whereby for the most part their concavity is diminished and they become colorless and transparent.[*] Vas has shown that in chronic tobacco-poisoning the number of red corpuscles is reduced, whereas the number of white corpuscles is increased. The action of the poison is particularly marked on the white corpuscles. Their motion, which on the artificially warmed slide continues, is, as the Hare experiments show, immediately retarded by the addition of nicotine; the blood corpuscle, on its part, breaks up into eight or more divisions, which from time to time separate and swim in the fluid independently of each other. These divisions are round in appearance and bear a strong resemblance to the red corpuscles. The globular shape which the white corpuscles often assume does not appear after the addition of nicotine, but the protoplasm remains without change in the condition in which it appeared when motion was suspended.

Nicotine exerts a direct action on the oxyhemoglobin, and it is probable that it is in the reduction of the latter that nicotine acts as a causative agent in the production of asphyxia. The disintegration of the red corpuscles described above points to the correctness of this conclusion; therefore, death following nicotine poisoning is not simply in consequence of the usual asphyxia from depression of the respiratory center *per se*, but is due to the fact that the hemoglobin fails to carry oxygen to the various parts of the body.

124 West Ninth Street.

ABSTRACT OF DISCUSSION

Dr. W. Forrest Dutton, Walker's Mills, Pa.: I have used the Riva Rocci instrument a good deal in recording these cases. I have not examined a large number, but I have examined enough to know that smoking, as a rule, raises blood-pressure and keeps it high for a considerable time. It would seem to me that the men and women working in a tobacco factory side by side would be affected in the same way; but this paper states that the men were affected by this particular eye affection and the women were not affected. I should like to have some explanation of that phenomenon for my own edification.

Dr. Francis Dowling, Cincinnati: I found, in my examinations in the tobacco factories, that the air of the factories does not produce either a toxic infection of the eyes or of the system in general of the employés. It was only in those who used tobacco in smoking or chewing that toxic symptoms were manifested. The reason the women are exempt is that they do not usually smoke or chew tobacco. I found that some of the men, on the other hand, smoked as many as 18 or 20 cigars a day, and the degree of tobacco infection, especially of the eyes, was usually proportionate to the amount of tobacco consumed.

FACTORS WHICH CONTRIBUTE TO A REDUCTION IN MORTALITY IN ABDOMINAL SURGERY [*]

F. F. SIMPSON, M.D.
Gynecologist to the Allegheny General Hospital, Consulting Gynecologist to the Columbia Hospital
PITTSBURG

In submitting this subject for discussion, I do not hope to offer anything new, but desire merely to present an outline, an approach to which has served to reduce my mortality and to improve my results in other respects.

In offering surgical relief in an individual instance, we should be prepared to give the following reasonable and adequate assurance:

First.—That the risk to life, as this particular operation is to be done, is not out of proportion to the gravity of the disease. What chiefly concerns a patient undergoing operation is the risk to which she is subjected by the given surgeon with the facilities at his command, and not the death rate from this particular operation as done by the masters of surgery. In surgery, as in every other sphere of human endeavor, the element of personal equation largely determines results—one operator will habitually have a low mortality, another will achieve an occasional brilliant result, while the work of still another will always be mediocre. The patient who submits to an abdominal operation stakes her life on the ability of the operator to command proper facilities and to do consistently high-grade work.

Second.—That if the patient recovers from operation, there should be no essential reason why she should not have the desired relief—i. e., that the patient should not be subjected to the risk of a grave operation if she can not be cured of the disease, as is the case in advanced cancer. It would be unwise, also, to remove a uterus for fibroid tumor, if coincident and grave cardiac, pulmonary or renal disease would almost certainly cause permanent invalidism, and if the depression incident to operation might easily prove fatal.

Third.—That the conditions under which operation is to be done should be such that no other combination of circumstances could offer less risk to life, or a greater degree of security against postoperative complications.

Fourth.—That in removing one type of pathology we may be able to avoid substituting another type which might readily entail greater discomfort and danger than that removed. A patient who exchanges a retroverted uterus for an incisional hernia or serious intestinal adhesions can scarcely be said to have profited by the exchange. Such unfortunate results will undoubtedly be encountered occasionally by the most careful, skilful, earnest and successful surgeons. If such occurrences are rare, it may be wise for a patient to take the slight risk—but if in individual hands they occur with marked regularity the risk under such conditions is manifestly out of proportion to the benefit which may be reasonably expected.

Fifth.—That no other less onorous kind of treatment could effect the desired result in a more satisfactory way. For example, salpingitis and pelvic peritonitis often may be completely cured by a relatively short period of rest and medical treatment. Precipitate removal of diseased organs under such conditions would be manifestly unwise. It often happens that a well-fitting pessary completely relieves the discomfort due to uterine displacements; on the other hand, one often finds the perineum so badly damaged that no type of pessary can be retained. Under these conditions safe surgical correction is desirable.

---

[*] Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Sixth.—That the benefit to be derived from operation should reasonably be expected to compensate the patient fully for the risk to life, discomfort, loss of time, inconvenience, degree and duration of disability, and the cost of operation and still leave a decided balance of benefit to the patient's credit. The simplicity of the procedure and the success of the operator in the surroundings and under the conditions which exist should be such as to afford adequate warrant for the belief that a high degree of success will attend this particular operation on this particular patient.

Just in proportion as a surgeon is accurate in these estimates will his judgment be good, his counsel wise, and his results satisfactory.

I am fully aware that such restrictions imply a degree of skill and judgment that it is difficult to acquire. Yet the moral law and statutes confer on us broad privileges in handling human lives provided we recognize and respect the sacred trust such privileges entail. If we respect those laws we must realize that many factors contribute to a high percentage of recovery with ideal convalescence. Chief among them are a due appreciation of the functional value of anatomic structures, a comprehensive knowledge of the principles of pathology, the recognition and correct interpretation of gross pathologic lesions in the living subject, an intimate knowledge of the habits and accidents common to the structures with which we come in contact, a correct estimate of the patient's reserve strength, a wise choice of time and type of operation, a rigid aseptic technic, a considerable degree of manipulative dexterity and such *ésprit de corps* among one's group of coworkers as will permit of operative speed and precision.

It is clear that to accomplish these aims necessitates a fortunate combination of time, adequate facilities, proper training, special aptitude, and assiduous application. Yet they are the requisites of uniform success and as such constitute the most important factors in the prophylaxis of postoperative morbidity and in the reduction of mortalty.

A comprehensive knowledge of the fundamental principles of pathology is essential to a correct interpretation of a given morbid process; to a forecast of its further course; and to a fair estimate of its present and future effect on the patient in question.

ACCURATE KNOWLEDGE OF THE NATURE, EXTENT AND TREND OF DISEASE

While it is practically impossible to make an exact diagnosis in every case before opening the abdomen, the careful and well-trained surgeon should be sure of the intra-abdominal condition in from 90 to 95 per cent. of cases. In estimating the needs of the individual patient it is not sufficient merely to know the nature of the disease for which relief is sought. One should know as well the influence it is having on the host, and also the extent to which it is modified by other pathologic processes affecting the individual. Should there be no other associated disease, it is still necessary to have exact knowledge regarding the lesion under consideration. The several stages through which the pathologic process passes, and the varying influence it exerts, make such knowledge essential to a wise handling of the disease.

Every type of pathologic process affecting the pelvic organs affords striking and frequent examples of the foregoing propositions. For instance, one's conception of early carcinoma of the fundus of the uterus which has scarcely invaded the muscular wall is entirely different from that of advanced adenocarcinoma of the cervix which quickly invades the parametrium and gives distant metastatic involvement. The treatment based on this conception differs quite as widely. Immediate hysterectomy in the first instance may be accomplished with little risk and is exceedingly likely to yield a radical cure. In our present state of knowledge one could hardly excuse a hysterectomy for advanced adenocarcinoma of the cervix and surrounding structures which would be attended by great risk to life and scarcely a possibility of even temporary relief.

One familiar with the progress and clinical aspect of varying types of uterine fibroids should reasonably expect to forecast the future course of events in an individual instance with the same degree of precision that the astute clinician anticipates complications in the course of pneumonia, diabetes, nephritis, arteriosclerosis, etc. For instance, if a patient of 37 or over has a growing interstitial or submucous fibroid, and for a year or more has lost an increasing quantity of blood, it is not necessary to permit the development of marked anemia with cardiac and vascular changes, nephritis, etc., before realizing that she represents a clinical type, tending inevitably to that end. On the other hand, a woman of like age or younger, with a small inoffensive subserous fibroid need not, at some risk, forfeit her chance of becoming a mother, by unnecessary haste in operation. A mere reference to such contrast of cases might seem out of place in this presence, and yet in my experience fully 40 per cent. of fibroids that have come to operation have shown some form of degeneration of the tumor, or serious cardiac, vascular or nephritic changes. Manifestly the time of election for operation comes before there is such debility as to retard convalescence.

The need for precise and comprehensive diagnosis is especially great in dealing with inflammatory affections of the genital tract—thus the outcome and hence the treatment may differ widely in such pathologic processes as true cellulitis with dense inflammatory exudate, on the one hand, and salpingitis, on the other. In each of these affections the best course to pursue may vary materially with the duration, extent and trend of the disease.

Equally wide differences in clinical aspects and treatment may arise in the course of such affections as ovarian cysts and tubal pregnancy.

EXACT DETERMINATION OF THE PATIENT'S RESERVE STRENGTH

The most frequent, the most perplexing and at the same time the most important decision the surgeon is called on to make relates to the margin of reserve strength possessed by the individual patient and the extent to which that margin will be encroached on by the method of obtaining relief. He must recognize the fact that a definite percentage of reserve strength is essential to the absolute needs of existence. It is evident that the energy that may with safety be dissipated by operation must come from this margin of reserve strength above the absolute needs of existence. The risk of operation increases just in proportion as this margin is encroached on. It is important that surgeons should analyze the composite picture of reserve strength and strive diligently to reduce it to an exact analysis. It is clear that this margin depends on the functional value of all the vital organs [illegible]culature.

It is usually [illegible] the functional value of each of these several structures by well-known clinical methods. To eliminate the element of chance it is essential that such clinical methods should be habitually and systematically employed. There would seem to be, however, a small percentage of cases in which the available tests are inadequate, notably those in which sudden death occurs in the course of what appears to be a perfectly normal convalescence, with or without evident fatal embolism; postoperative nephritis occurring in what appeared to be previously healthy kidneys; and rare evidences of death due to acidosis, the urine having previously been free from sugar, diacetic acid, and other abnormal constituents.

JUDICIOUS ADAPTATION OF TIME AND TYPE OF OPERATION TO INDIVIDUAL NEEDS

The wise adaptation of the time and type of operation to individual needs is essential to uniform success. It demands prompt decision and constitutes the severest test to which a surgeon's judgment is put.

It is not always easy to refrain from surgical intervention when a patient lies critically ill and is apparently growing worse from an intra-abdominal affection which will clearly demand operation at some stage of its existence. Yet if we except accidents and injuries to hollow viscera—strangulated hernia, perforation, etc. —it seems clear to me that an increasing percentage of so-called emergency work can be reduced to the safer planes of incomplete and elective surgery. In all surgery there is scarcely a more hazardous procedure than the removal of a large universally adherent, infected ovarian cyst at the height of an acute and exhausting illness. It often happens, however, that evacuation renders subsequent removal simple and safe. At times such an emergency as torsion of the pedicle of an ovarian cyst is rendered more serious by a severe complicating nephritis. To withhold surgical relief may seem a hazardous procedure and yet it is often surprising to see the marked improvement which follows delay and restored renal activity. It occasionally happens that the completion of an operation would probably prove fatal, whereas temporary failure may later be followed by safe operation.

When pronounced anemia and cardiac and renal complications accompany uterine fibroids the most gratifying results are often attendant on a few weeks of preliminary treatment. A number of patients who had for some months been going progressively down until they were almost exhausted have improved sufficiently to permit of safe hysterectomy and speedy convalescence, whereas more precipitate operation might readily have proved fatal.

My conviction daily grows more firm that by converting acute inflammatory affections of pelvic structures into aseptic lesions the need for operation and the postoperative morbidity and mortality may be greatly reduced. This conviction is based on an increasing number of complete recoveries without operation and a series of 475 consecutive abdominal sections for inflammatory lesions of tubal origin with only four deaths.

When operation is done while inflammatory exudate still infiltrates intestinal walls, injury with subsequent fecal fistula, adhesions and intestinal obstruction, are far more common than when internal sterilization of pus (tubes) is practiced. In the series of cases just referred to (475 sections for quiescent inflammatory products) there have been only two cases of partial intestinal obstruction. One of these was subsequently relieved by operation. The other did not require it. These four complications occurred in cases in which operation was done relatively soon after the acute attack had subsided—that is, just as the last of the exudate was being absorbed. During the period in which these sections were being done for inflammatory lesions something more than a thousand sections were done for other types of pathology without a single fecal fistula, and, so far as I know, with only one case of partial intestinal obstruction, which occurred two years later.

A GROUP OF COMPETENT COWORKERS

I consider the proper organization of a surgical service an important factor in the reduction of mortality. The method which seems entirely satisfactory in my service at the Allegheny General Hospital consists in dividing the work into several departments and having a corps of competent and continuous workers in each. The corps of workers consists of:

1. A thoroughly reliable and efficient first assistant is, I believe, essential to quick, precise work and uniform success. Dr. S. A. Chalfant, who was anesthetist for a considerable period of time, has occupied the position of first assistant for a number of years.

2. A skilled anesthetist, on salary, who, in addition to giving all anesthetics, is responsible for a typewritten record, embodying all details regarding diagnosis, operation, pathologic lesions found at operation and a description of specimens removed. It is his further duty to keep tabulated records of postoperative facts in any way due to the administration of the anesthetic.

3. A pathologic department consisting of an expert pathologist cooperating with the pathologist of the institution and having a competent salaried assistant. Among other things, it is customary to have routine examinations of blood at stated intervals before and after operation, and at other times if occasion arises; to examine the urine before operation and each 24 hours thereafter for two or three days, or as long as any abnormal constituents are found. The routine urinalysis embraces among other things a quantitative estimate of the acetone bodies both before and after operation; systematic bacteriologic investigations and histologic examinations of specimens and discharges are made.

4. The Nursing Corps.—Much depends on the proper organization of one's corps of nurses. A group of intelligent, earnest, systematic, diligent nurses, who take a deep personal interest in promoting the comfort, security and welfare of each patient, contributes much to the efficiency of one's work. The arrangement we have had at the Allegheny General Hospital has proved satisfactory in method and personnel. (a) There are efficient graduate head nurses in charge of the private and ward floors. They have the usual group of undergraduates. (b) An unusually competent graduate nurse has for a number of years been in charge of the operating room and of the preparation of all dressings used therein. She also prepares the field of operation in clean cases. She has two undergraduate assistants. (3) A plan which I can not commend too highly is the employment of a continuous group of postoperative nurses chosen because of especial aptitude and fitness for this particular type of work. Each patient subjected to abdominal section should be under the care of such a competent graduate day and night nurse for the first 48 hours, or as much longer as the patient's condition may demand. They add much to the comfort, and, by being

skilled and alert, to the safety of patients. Private patients gladly pay for this service—the hospital supplies it to charity patients.

MINIMUM AMOUNT OF ANESTHETIC

Undoubtedly one of the most important advances in major surgery during the last century was the introduction of anesthetics. During the last decade one of the most important advances has been the uniform and progressive tendency to reduce the quantity of anesthetic. This has resulted from a better understanding of the frequency, nature and extent of the deleterious effects they cause. It has been accomplished by the employment of skilled anesthetists, by the adoption of better methods of administration and by such improvement of team work in operative technic as reduces the duration of operation.

While fully recognizing the extent of our indebtedness for anesthetics, and to those who introduced them, we must not lose sight of the fact that, while doing immense good, anesthetics usually cause distinctly harmful results. These results are expressed in a definite clinical picture which is always present but in varying degrees. One almost invariably sees marked muscular depression and interference with glandular secretion as evidenced by parched lips, intense thirst, usually nausea and vomiting, and a reduced quantity of urine.

When this disturbance is more marked the air passages may become affected, the circulatory system depressed, metabolic disturbances occur, and hepatic and renal functions may be markedly or even seriously vitiated.

The more thoroughly one investigates these subjects by careful observation of symptoms and systematic preoperative and postoperative analysis of secretions, the more fully does one realize that the anesthetic is perhaps the most important factor in determining operative mortality. The truth of this proposition has repeatedly been demonstrated to my entire satisfaction by contrasting the postoperative condition of two classes of patients: The one class embraces such operations as appendectomy, cholelithiasis, hysterectomy for fibroid, etc., on good subjects under ether anesthesia. The other class includes a number of patients operated on for gallstones, large adherent ovarian cysts, appendicitis, etc., who were also the subjects of such grave cardiac, renal or pulmonary disease as positively contraindicated the use of a general anesthetic. The observation has been so common as to be almost universal, that in the grave cases without anesthesia the patients were some hours later, in much better condition than the patients in the simpler cases to whom ether was given, and that convalescence was almost uniformly more smooth and satisfactory. I would emphasize the fact that this striking difference was in favor of the patients who would almost certainly have died had a general anesthetic been administered.

The method we have found most satisfactory has been the continuous services of a skilled and salaried anesthetist who uses the open or drop method, with the coincident administration of oxygen, using a soft catheter introduced through the nose. The use of oxygen in this way has, among other things, almost done away with nausea and vomiting.

I believe that a full appreciation of the possible harm that might result from the administration of anesthetics, and a careful study of the circulatory, respiratory and urinary tracts before operation, has contributed no little to the maintenance of a low operative mortality in my service. It has also done much to reduce the frequency and severity of such postoperative complications as are attributable to this cause. Pneumonia and bronchitis are exceedingly rare; shock and other circulatory disturbances are almost never seen, and urinary complications are much less frequent and serious than formerly. There have been only 13 deaths (1.86 per cent. mortality) in the last 700 consecutive laparotomies.

RIGID ASEPTIC TECHNIC

A rigid aseptic technic is unquestionably the foundation on which all modern surgery rests. Without it there can be no uniform success. Without it the certainty, nature and extent of postoperative complications is such as to render elective surgery rarely, if ever, justifiable. The development of a rigid aseptic technic demands that the surgeon, his assistants and all others who come in contact with the field of operation during the period of preparation, operation or postoperative care, shall absolutely avoid contact with any wound, dressing, receptacle, or other structure or article which is not surgically clean. This implies the use of sterile rubber gloves in all physical examinations of patients, presumably free from open foci of infection. It implies even more rigid care in examinations made in the presence of discharges from open wounds. Uniform aseptic success demands that such precautions be taken every day in the year; so that the most important instruments concerned in operation, the hands and their covering, shall remain as nearly aseptic as possible. The hands having been kept continuously clean, the risk of infection is further reduced by the use of well-fitting rubber gloves of good fiber. These principles apply with equal force to the operator, his assistants, the nurses in the operating room and those who have the care of the field of operation. Such a rigid aseptic technic forces on us recognition of the undoubted fact that hospitals are clearing houses for all types of infection. With rigid technic, proper segregation of patients, and such division of labor as precludes the intermingling of caretakers of septic and clean patients, it is easily possible to do elective work with uniform aseptic results. We should never lose sight of the fact, however, that when the least relaxation occurs the conditions are analogous to those which exist when a powder mill and a match factory are operating under a single roof.

SPEED WITH PRECISION

If a surgeon is called on to operate at a distance, in a definite and considerable percentage of cases, he will lack essential facts which should guide him in deciding for or against operation, the type of procedure to be employed, and the time of election and the conditions under which it should be done. If he operates under such conditions, the death rate will be unnecessarily high. If he declines to operate, an embarrassing situation arises.

I can not too strongly commend the wisdom of operating habitually in one's accustomed surroundings. By doing so and exercising constant effort to develop systematic methods, it becomes possible to have the duties of one's coworkers proceed with clockwork precision.

With such a well-organized corps of workers, the division of labor may reach such a degree of efficiency that the operator may concentrate his entire attention on his individual work—arriving with unnecessary interruption at prompt decision regarding the fate and function of structures, the type of operation best suited to individual needs, and essential methods of technic.

By such an arrangement, one will more uniformly do the operation best suited to individual needs; good team work, celerity and precision reduce the time required for operation, the quantity of anesthetic employed and the possibility of such accidents as slipping ligatures, losing pads, peritonitis, infected pedicles, stitch abscesses, etc. In one's accustomed surroundings, where a definite, systematic and careful technic is employed, it is rarely necessary to improvise. He is a poor surgeon who can not improvise if an emergency demands it. He is a poorer one who habitually or frequently allows himself to be placed in such a position that he must improvise. The act of improvising is evidence that an operator is substituting an inferior method of procedure for one he would prefer to employ in the individual case. While untoward results may rarely follow, ample room exists for the element of chance to enter.

The evolution of systematic methods and technic employed in operating rooms will necessarily vary according to individual requirements. The simple technic which has proved satisfactory in my operating room at the Allegheny General Hospital is briefly as follows:

In order to reduce the chance of transmitting infection to a minimum only three persons are supposed to have clean hands—the operator, the first assistant, and interne; they scrub their hands with soap and running water for twenty minutes, and then use such chemical antiseptics as will not injure the skin. Solutions of potassium permanganate, oxalic acid, bichlorid of mercury and, finally, alcohol being the sequence preferred, but if either of these solutions is irritating to the skin it is omitted.

All instruments and dressings used during operation are taken directly from the sterilizer by the first assistant. The arrangement of dressings and of instruments in trays and on tables is always exactly the same, thus enabling any one connected with the operation to find a desired article without a moment of hesitation.

In order to avoid unnecessary handling and consequently arousing of patients, they are anesthetized on the operating table, which is then rolled into the operating room.

While the first assistant is arranging instruments and dressings, the head nurse has the patient placed in proper position so that the interne proceeds at once to cleanse the field of operation. While the operator adjusts protecting sterile cloths, the first assistant verifies the count of abdominal pads and the head nurse places the instrument and dressing tables in their respective places.

The instrument table is placed within reach of the operator; as the instruments always occupy exactly the same position in the several trays it is easy to pick up any desired instrument without even turning the head. The first assistant having verified the number of pads available for use, must account at the end of operation for the number, which must always be a multiple of five. In order to avoid error, as soiled pads are discarded, the head nurse has one of her assistants collect these pads and pin them together in sets of five. These sets are then arranged in definite order so that with the greatest economy of time the head nurse may at any moment give the correct count of discarded pads. To this number the first assistant adds those in his keeping. If the aggregate is not a multiple of five, one or more pads must be found within the abdomen or elsewhere. So far as we know, a pad has never been left within the abdominal cavity, though without such a definite system I am confident such an accident would probably have happened.

The instruments, needles and suture materials are in the hands of the interne. It is our desire to simplify methods so far as possible, so only four types of needles are used. Each needle has its definite purpose. It always carries its definite kind of sutures—the suture material employed is limited to silkworm gut, celluloid linen No. 1, and the finest catgut, that will give a fair degree of tensile strength. We usually employ commercial catgut which is contained in hermetic glass tubes and is supposed to be sterile. Before using, however, the tubes are boiled for half an hour on two successive days.

It is my belief that the head nurse can accomplish most by being free to adjust the patient, to arrange instrument and dressing tables, irrigating stands, solutions, intravenous sets, hypodermics, if needed, supervise the counting of pads, send specimens to the laboratory for immediate frozen section, etc. We accordingly prefer that she should not have sterile hands.

The head nurse and her two assistants make all dressings used in the operating room—and see that a supply of all appliances used is constantly at hand.

It is our desire to make the postoperative treatment of patients as simple as possible, especially to minimize, so far as possible, the petty annoyances which disturb patients unnecessarily, etc. They are kept as quiet as possible, they are rarely catheterized—ice is usually applied to the abdomen—continuous enteroclysis, normal salt solution, Murphy method often serves a valuable purpose. The patient's position may be about what she wishes, unless there is some especial reason to avoid moving, such, for instance, as the use of drainage.

CONCLUSIONS

In conclusion, I believe that an accurate knowledge of the nature, extent and trend of disease, and exact determination of the patient's margin of reserve strength; a judicious adaptation of the time and type of operation to individual needs; a group of competent operative coworkers; a minimum amount of anesthetic; a rigid aseptic technic; and speed with precision, are factors which will yield a low mortality and highly satisfactory operative results.

ABSTRACT OF DISCUSSION

Dr. C. A. L. Reed, Cincinnati: Operative celerity consistent with the safety and precision of operation, with reference not only to minimizing the time but the amount of the anesthesia, is a matter that cannot be emphasized too strongly. I was invited for three o'clock one afternoon some time ago to witness an operation that was done in the patient's house, where it ought not to have been done. I arrived nearly half an hour late, expecting that the hysterectomy would have been concluded. I not only was not too late, but I had the opportunity of holding a coal oil lamp for over an hour after nightfall until the operator got through with his work. It is needless to say that the patient died. Recently a patient was kept under anesthesia for a simple perineorrhaphy for 2½ hours. Operations of that kind are being done with a frequency that is alarming, and the sooner this Association states its disapproval of this slovenly method the better. I have been in operating theaters, with good operators in charge, in which I have seen the surgeon, instead of paying strict attention to his business, engage in conversation with those about him, while the patient was being kept under an anesthetic, thus unnecessarily and dangerously prolonging the period of operation. I recall with pleasure that celerity was one of the great points constantly emphasized and exemplified by the late

Lawson Tait, than whom no more successful operator ever lived. Those who had the privilege of seeing him operate will recall with what promptness he did his operations, with what general precision they were done, and all will testify to the high grade of his results. The point to which he constantly called attention was the importance of minimizing the anesthesia with reference to sparing the patients from metabolic difficulties due to taking too much anesthetic. The time has arrived to proclaim, and I think the protest should go forward in no uncertain terms, that that surgeon who consumes an unnecessary amount of time in the performance of the operation subjects his patient to an unnecessary danger. Therefore, when a surgeon begins an operation, let him begin and pay attention to his business and keep at it until the work is safely done. And this reminds me that there are other phases of the question, either actually raised or suggested by Dr. Simpson's paper—and that is as to the question of surgical competency. This is an issue that we have been dodging in one way or another for a long time. It is one that nobody likes to take up. But we all know that a lot of surgery is being done by a lot of operators who are not qualified for the work. I shudder when I think of the possible unnecessary mortality due to this cause. In one of the states, Colorado, I believe, a bill was introduced last year that was intended to put a curb on this abuse by establishing a supplementary state license on surgery. I don't know what came of the bill, but I do know that the mere fact that such a bill was framed shows that the public is taking cognizance of the fact that general medical qualification does not always imply special surgical qualification. The fact is that surgical work is being cheapened by average amphitheater exhibitions. There is too much of this thing of going for a day or a week "to see the Mayos" or "to see Murphy," or "to see Richardson," or "to see Matas," and then coming back a full-fledged surgeon. The postgraduate schools with their semi-diploma certificates are far from being without responsibility for this situation. The fact is that the "smatter-courses" ought to be suppressed. Let us get to the point of thoroughness, to the point of apprenticeship, to the point of broad fundamental culture, to the point of careful manual training, and away from the irresponsible promiscuity that now too much characterizes the surgery of this country.

Dr. J. H. Carstens, Detroit: The patient should be carried into the operating room and anesthetized without having time to think of the operation. The shock and dread kill many patients. Another point that I wish to make is that slow operating is bad practice. No one can operate with gloves so quickly as without, so I operate with my bare hands. I see men do all kinds of operations with gloves on. These often tear during the operation and naturally will infect the patient. In order to do good rapid surgery one must have asepsis and absolutely clean hands all the time, and that means that the surgeon must not at any time put his fingers into a dirty place. If he ever gets his hands contaminated it will take many weeks to get them clean, no matter what the antiseptic or what amount of scrubbing he employs. If I make a mistake in diagnosis and find that I have a pus case I quickly put on gloves.

Dr. H. J. Boldt, New York City: Dr. Simpson said that operators should be careful to make an exact diagnosis in cases in which they intend to operate. That is very nice and while an exact diagnosis should be made in 95 per cent. we must not put the burden on the operator so much as the teachers who are connected with schools sending out men who are in time to be operators. A great many men who enter the field of surgery take a postgraduate course of six weeks or two months and go out, considering themselves specialists in certain lines of work. It is not possible that any one can learn a proper technic in so short a time. Pupils in their senior year should be taught how to make diagnoses. The method of treatment will come of its own accord if a correct diagnosis is made.

Dr. C. S. Bacon, Chicago: It seems to me pertinent to call attention to the proposition that a special license be required for surgical operators. Last year such a measure was presented to the legislature of Colorado, but it was not endorsed by the profession. It, however, shows the trend of the times and undoubtedly there will be a great deal more proposals of the same kind in the future. The importance of proper training in diagnosis and especially in surgical technic is admitted by all. Does every one who receives a license to practice possess such training? We all know that he does not and it is manifestly not right that every one should have the license to perform all sorts of operations.

Dr. F. F. Lawrence, Columbus: One contributory factor in shock which has not been mentioned is unnecessary traumatism. I care not whether it be by stuffing the abdomen full of gauze or by bruising the tissues with retractors. Every surgeon should teach that such unnecessary trauma is unsurgical. What useful purpose can a lot of gauze stuffed into the abdomen serve? None. There is seldom any necessity for putting a metal retractor in the wound. If there is a bleeding vessel down in the wound or in the pelvis or back in the mesentery it may be necessary for a moment only. When we teach that we must prevent every unnecessary trauma we will save our patients shock and forestall one of the elements of infection. There can not be infection in normal tissue.

Another thing: Operations should be done in a dry field. Sterilizing should be done the night before, a double sterilization; germs grow only in a moist soil. Ligatures should not be tied too tight. Strangulated tissue is dangerous and no matter how slight the strangulation may be it causes shock.

Dr. Robert T. Morris, New York City: We are now on the verge of a fourth era of surgery. The first era was heroic. The next, anatomic. The third, now prevailing over the world, is the pathologic, in which we expect by mechanical measures to remove the causes and products of infection. The fourth era, on which we are just now entering, is the physiologic, which includes the idea of conserving all the natural resistance of the patient and allowing him to do what we have tried to do in a crude way mechanically. If we are to allow the patient to do this by conserving his self-resistance, we are to accomplish it by avoiding all the causes which shock the machine which is making phagocytes and opsonins. The patient has no other business. His business immediately after operation is manufacturing and if we interfere with the work of this machinery by long-continued operation, by long and unnecessary technic, by performing taxidermy on a patient with gauze, we prevent that patient from manufacturing his phagocytes and opsonins. An important point among those brought out by Dr. Simpson is asepsis. If I were anchoring a floating spleen I would wear a mouth mask, cap, and rubber gloves. If I were operating on a case of appendicitis with abscess, I would not wear a mouth mask, or a cap, or rubber gloves, and it would make no difference whether I washed my hands after the operation or before. If pus were spread on the normal peritoneum in the course of the operation I would leave it there. I would get in and get out. I would leave the patient with a normal resistance which would care for that pus so much better than I could care for it that his chances for recovery would be very much increased. In anchoring the spleen we might take twenty minutes for the operation; but for the pus case with appendicitis, we should not make the operation longer than five minutes if possible.

Dr. Horace G. Wetherill, Denver: The established immunity which occurs in certain acute cases is important and frequently such patients should be tided over the acute stage. The general tendency of the last few years has been to do this with certain peritoneal infections, notably with those from appendicitis. Far too many operations have been done for acute pelvic infections and often with extremely bad results. The bill which Dr. Bacon referred to for the control of surgical operations was presented in the legislature of the state of Colorado. It was not approved by the local medical profession. As president of the Colorado State Medical Society I presented a plan which, for us, seems much better. In the west the hospital situation is different from that of the east. We have a hospital staff; but the work in the hospital is not limited to the staff. Any physician may take his patients into the hospital and do as he pleases. My proposal was that each of the hospitals in our cities appoint a representative, these representatives to form a body to be known as a sort of hospital clearing house association representing all the hospitals in the community. Among other duties of this body every one wishing to take patients to the hospital must make application to this clearing house association. He must present his credentials, tell with whom he has worked, what his work has been, and in a broad way what his qualifications are. On such application made to this board his practice in the hospitals must depend. In many communities that is a plan which would meet this difficulty.

DR. JOHN A. MCGLINN, Philadelphia: I want to emphasize Dr. Boldt's statement in reference to diagnosis, and to urge the necessity of teaching and training students to be diagnosticians rather than operators. I feel that clinics made up of major operations are useless. The students can see but little of the technic, yet it gives them confidence to attempt work for which they are not trained. The time could be much better devoted to practical work in diagnosis. While I do not minimize the necessity of speed in operations I feel that completeness is a far more important factor. Recently I operated on a patient with double pyosalpinx several weeks after a general surgeon had removed the appendix. Within the past year a colleague operated on a patient with ruptured tubal pregnancy ten days after a very able surgeon had removed the appendix. These two cases are sufficient I think to prove the necessity of sacrificing speed to thoroughness in our work. The matter of anesthesia is important. I do not believe that it is advisable to allow the resident physician or an untrained man to give an anesthetic. I have always looked on the giving of an anesthetic as important as the operation itself. For this reason I have always employed a trained anesthetist. With reference to asepsis, I feel that the fewer assistants one has the better will be his results in an aseptic field. I use but one assistant for all operations and he has very little to do. He is simply used as an extra pair of hands to hold some instrument such as a retractor. One can train himself to work rapidly with few assistants, depending on himself for almost everything.

DR. F. F. SIMPSON, Pittsburg, Pa.: My object in bringing this subject before the Section was to get just what we have had, a definite expression of opinion by operators. Relative to some of the factors concerned in the reduction of mortality I would say that the synopsis that I have read is merely an abstract of my paper which will be published in full and a good many of the points brought out by the discussion have been more fully dealt with than the abstract indicates.

In regard to the reduction of mortality as related to the anesthetic, the opinion I wished to convey was that a study of the deaths during the last four or five years would show that probably one-third of the deaths could be attributed directly to the anesthetic, that is, to the effect of the anesthesia in disturbing metabolism, and its influence on the kidneys and on the liver. The more fully we study the subject of acetone bodies and the effects of metabolic disturbance the more do I believe that the anesthetic and its effect on metabolism will probably be found to be the cause of a high percentage of the deaths that actually occur.

VACCINE AND SERUM THERAPY IN CHILDREN*

CHARLES GILMORE KERLEY, M.D.
Professor of Diseases of Children, New York Polyclinic Medical School and Hospital; Attending Physician to the New York Infant Asylum and Maternity; Assistant Attending Physician to the Babies' Hospital, New York
NEW YORK

Vaccine therapy for prevention or cure of infection has for its object the production of an active immunity to the specific bacteria concerned, while serum therapy produces a passive immunity only.

Immunity, which is resistance or lack of susceptibility to a given disease or micro-organism, may be natural or acquired. Artificial or acquired immunity may be the result of an attack of the disease itself or it may follow inoculation with living cultures of micro-organisms in sublethal doses or in an attenuated state, with dead cultures or with those products of the growth and metabolism of bacteria known as toxins. Immunity so acquired is active or direct, comparatively slow in appearance, and of comparatively long though variable duration. It is brought about by the development in the blood serum of substances antagonistic to the vital activity of the bacteria or to the toxins. Such substances are known as antibodies. The serum of an animal which has been actively immunized and which is rich in antibodies may be inoculated into another animal for the purpose of combating infection. The immunity thus produced in the second animal is indirect or passive and of comparatively short duration.

The antibodies are of several kinds: agglutinins, opsonins, precipitins and lysins. They are formed by the tissue cells under the stimulus of the infecting bacteria, at first locally, then generally, and are present in the serum and to a lesser extent in the other body fluids. They manifest themselves in certain definite ways demonstrable and measurable by laboratory methods: agglutination reaction, opsonic index, bactericidal reaction, and the complement deviation test. Clinically their increase is accompanied by amelioration of the symptoms of infection. The aim of both vaccine and serum therapy then is to aid the production of antibodies in order to effect a destruction of the invading bacteria and the neutralization of their toxins. Metchnikoff asserted that the destruction of micro-organisms was brought about by their ingestion by phagocytes, especially [illegible] leucocytes. Denys and Leclef have pro[illegible] substance in the blood serum which prepares the bacteria for phagocytosis. This sensitizing substance was named "opsonin" by Wright and Douglas, who elaborated methods for its study in the laboratory and for its practical application to the treatment of infections by means of vaccines made of suspensions of dead bacteria.

It has been found in general that the opsonins are below normal at the onset of an infection and during the height of the acute stage, and that, as improvement occurs, the amount of opsonin in the blood serum increases. The administration of dead cultures of the bacteria causing the infection stimulates the production of opsonins, as proved by improvement in the symptoms and rise in the opsonic index.

TECHNIC

In order to estimate the opsonic index it is necessary to prepare serum from the patient, serum from a normal person, leucocytes from a normal person, and a culture of the bacteria from the patient's lesion.

Serum is readily obtained by pricking the finger and catching the blood in a small curved glass tube, as recommended by Wright. The blood is allowed to clot in the tube, and the resulting clear serum is removed by means of a capillary pipette, which is then sealed at its narrow end. The test should be made as soon as possible after drawing the blood, preferably within twenty-four hours.

Leucocytes are obtained from ten drops of normal blood caught in a tube containing 10 c.c. of 1.5 per cent sodium citrate in normal salt solution. The mixture is centrifuged and the fluid carefully drawn off and replaced by normal salt solution in order to wash the blood cells free from serum. After centrifuging again the supernatant fluid is removed and the upper layer of white blood cells taken up into a capillary pipette, whose lower end is then sealed in the flame. This is known as the "leucocytic cream."

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The suspension of bacteria is made in normal salt solution from an agar culture not over twenty-four hours old. It must not be too thick and should be free from clumps.

Capillary pipettes of similar caliber having been selected, equal quantities of patient's serum, leucocytes, and bacteria are drawn up and thoroughly mixed in one, while normal serum, leucocytes and bacteria are drawn into another. A control, using normal salt solution instead of serum, should also be made. The pipettes are sealed below and incubated for fifteen minutes at 37 C. The mixture is then expelled on a glass slide, thoroughly mixed again, and spread on clean slides. After fixing in methyl alcohol and staining in methylene blue the slides are placed under the microscope and the number of bacteria contained within fifty leucocytes is counted. This gives the phagocytic index and the quotient of the patient's and the normal phagocytic indices equals the opsonic index of the patient. More satisfactory results have recently been obtained by making the tests with diluted serum, according to Neufeld. The opsonins in the normal blood serum used for control are found to disappear in a lower dilution than do the immune opsonins in the blood of the patient who has been immunized by the disease or by the administration of vaccines.

The vaccine is made by suspending agar-cultures less than twenty-four hours old in normal salt solution. Equal quantities of bacterial suspension and of blood from a normal person are drawn into a capillary pipette, mixed, and thinly spread on a slide. The red cells and the bacteria are then counted in a number of fields. Since the normal blood contains 5,000,000 red cells to the cubic millimeter, the number of bacteria in proportion to the red cells can be estimated per cubic millimeter, and the actual count per cubic centimeter readily calculated. The tube containing the bacterial suspension is sealed and heated for two hours at 60 F. Control cultures are then made to test the sterility of the undiluted suspension. This having been properly accomplished, the vaccine is diluted in bottles of sterile normal salt solution, sealed with a rubber cap and paraffin, according to the dose desired per cubic centimeter. Thus, if the actual count showed that 5,000,000,000 bacteria were present in 1 c.c., diluting the vaccine fifty times by adding 1 c.c. of undiluted vaccine to 49 c.c. of sterile salt solution, would make a vaccine containing 100,000,000 bacteria in 1 c.c. Injections of 1 c.c. or less are made into the shoulder, back or thigh under strictest aseptic precautions.

Diphtheritic serum and the Flexner serum are both well known and require no comment.

RESULTS IN VARIOUS INFECTIONS

Staphylococcus Infections.—It is in these cases that the vaccine treatment has given the best results. While it is always wise to use a vaccine prepared from the patient's own strain of staphylococcus, it is not absolutely essential that this be done. Any stock vaccine which has given good results in a similar case may be used, provided that it has been proved by a culture made from the pus of the patient's lesion that staphylococci are the causative factors. It is essential also to know whether the *Staphylococcus aureus* or *albus* be present, in order that the appropriate vaccine may be employed. The dose in infants under one year should vary from 7,000,000 to 15,000,000 of dead cocci, and in infants between one and two years 15,000,000 to 20,000,000 may be given. In children over three years of age 20,000,000 to 50,000,000 may be used. The inoculations are repeated on the sixth to the tenth day if necessary. When the opsonic index is estimated throughout the vaccine treatment of such a case it is observed that a slight fall in the index follows the injection and that it may be accompanied clinically by a slight feeling of malaise, but no rise of temperature should occur. This constitutes Wright's negative phase of the reaction of immunity, and is followed in one to several hours by a rise in the index and improvement in the clinical symptoms. As soon as the opsonic index begins to fall below the normal on the fifth to the tenth day another injection is indicated. As a matter of fact, the test for the opsonic index has been found to be too uncertain to make it practical and worth while to follow systematically, the clinical symptoms being sufficient indication of the value of the vaccines. Too rapid or too large dosage must be avoided, because there is danger of exhausting the responding power of the human organism by overstimulation. The temperature should be taken before the vaccine is injected, and every three hours during the following twenty-four.

Furunculosis: In young infants this has proved readily amenable to treatment by staphylococcus vaccines. Improvement is shown by a much more rapid healing of the furuncles already incised and by the non-appearance of new ones. After the second inoculation improvement is the rule. The amount of pus is lessened and fewer dressings are required in cases so treated. No bad effects from the injections have been noted. It is best to begin with a small dose and increase if necessary.

Acne: Excellent results have been obtained by some observers; others report negative results. Larger doses are usually necessary.

Otitis media of staphylococcus origin: In this disease vaccines are reported, evidently by enthusiasts, as having proved of value, as also in suppuration in the antrum, in styes, in osteomyelitis, and in empyema. It is asserted that in the latter disease operation may, in rare and favorable cases, be obviated by the vaccine injections. After operation the vaccine is said to be of service in aiding the more rapid disappearance of pus from the pleural cavity and hastening the healing of the wound.

Any local suppuration due to staphylococci is benefited rapidly by vaccine administration. In general septicemia the results have been encouraging (Wright).

Streptococcus Infections.—In all cases of streptococcus inflammations the results of vaccine therapy have been far less brilliant than in staphylococcus cases, but still encouraging enough to warrant their further use. It seems to be essential also, far more than in the staphylococcus injections, that the vaccine be prepared from the strain of streptococcus isolated from the patient. The dose is about one-third that of the staphylococcus, 2,000,000 to 3,500,000 in babies under one year of age, 5,000,000 to 7,000,000 between one and two years, 10,000,000 to 30,000,000 in older children.

A boy, two months of age, developed an abscess on the chin. This healed after incision, but was rapidly followed by a suppurative epiphysitis and periostitis of the right tibia and of the sternoclavicular articulation on the left side, together with two areas of subperiosteal involvement of the occipital bone. The right tibia separated from the remainder of the limb at the epiphysis and was removed, a new bone forming in its place. The bone abscesses healed and others continued to form at intervals during the next ten months. It was decided to employ vaccine made from the pus to control the infection. The infecting bacteria were found to be the streptococci. The vaccine was made by Dr. Hastings and seven injections were given of 9,000,000 to 20,000,000 bacteria of four days apart, 90,000,000 in all.

No improvement whatever was made on the infection. The abscesses continued to form and new bone areas became involved under the treatment.

I am sure that in this case the vaccine was used in too small dosage.

Erysipelas: In erysipelas Shorer finds that the course of the disease is apparently shortened by the inoculation of dead streptococci, but that neither migration nor recurrence seems to be prevented.

Scarlet Fever: In scarlet fever the opsonic index to streptococci has been studied by Tunnicliff, who finds that it is below the normal at the onset of the disease, but rises when the acute symptoms subside. As local streptococcus complications appear the index falls once more. Favorable results following the injections of dead streptococci in cases of scarlet fever have not thus far been reported. On the other hand, in local streptococcus inflammations—adenitis, otitis media, and osteomyelitis—the treatment has given most encouraging results.

Gonococcus.—In vulvovaginitis due to the gonococcus in young infants under one year of age, the injections of dead gonococci have had no effect in shortening the course of the disease, in lessening the amount of discharge nor in causing the cocci to disappear from the vagina. In older children Hamilton and Cooke have found that the effect of the dead gonococcus injections is more marked in chronic than in acute cases, the disease being very decidedly shortened in its course. The later stages of the acute cases were also shortened, while no result was noted in the first weeks of the attack. Hamilton and Cooke observed no advantage from the use of a vaccine made from the patient's own organism. The initial dose of 5,000,000 was gradually increased to 40,000,000 or 50,000,000, according to the needs of the case. Injections at eight-day or nine-day intervals proved best.

Pneumococcus.—The few cases of pneumonia in which dead pneumococci have been injected showed no marked advantages over untreated cases. In empyema of pneumococcus origin healing has been hastened by inoculations of dead pneumococci (Ross).

Meningococcus.—In cerebrospinal meningitis, due to the meningococcus of Weichselbaum, vaccine therapy has been tried, but it has become superfluous in view of the brilliant results obtained by means of the antimeningococcus serum of Flexner and Jobling.

Bacillus Coli Communis.—Inoculations of dead colon bacilli in doses of 10,000,000 to 50,000,000 are reported to have given excellent results in cases of cystitis due to that micro-organism. The symptoms subside rapidly and the bacilli disappear from the urine in a comparatively short time.

Typhoid Bacillus.—Injections of dead typhoid bacilli have been employed as a prophylactic measure in the English army with fair results. As a curative therapy in children they have not, thus far, been used.

Pseudodiphtheria Bacillus.—In otitis media due to this organism Dr. Tunnicliff obtained apparent benefit in some cases by injecting the dead bacilli. The attack of otitis was postscarlatinal and acute.

Tubercle Bacillus.—Local tuberculous lesions have been treated by injections of tuberculin in very small doses with good effect. This is true of chronic local tuberculosis without constitutional symptoms, especially in bone, joint, gland, skin and eye affections. In pulmonary tuberculosis of a chronic type, running a nearly apyretic course, tuberculin is also of value. In all acute tuberculous lesions with marked fever and general symptoms tuberculin therapy has proved useless and it may be attended by grave danger. The dose of crude tuberculin administered for purposes of immunization in a chronic tuberculous lesion should be very small, 1/5000 of a milligram, gradually increased to 1/2000, 1/1000 or more. The inoculations should be repeated not oftener than once in ten days, at first, and the temperature carefully measured every two hours. If a rise occurs the dose has been too large, and must be reduced at the next injection. In selected cases of bone and joint disease and also in adenitis, good results have followed six or eight months of continued treatment, the dose being gradually increased in amount and the intervals shortened to three days. Wright maintains that the opsonic index is an essential guide to the regulation of the dosage. Other observers are satisfied that the clinical reaction is a sufficiently accurate guide. The opsonic index to the tubercle bacillus is low in cases of tuberculosis, unless it fluctuates, owing to autoinoculation from an active lesion. It is the office of the treatment to raise the index permanently.

In an unpublished paper Dr. Raymond Hoobler of New York presents nine cases of different diseases in children treated with vaccines. Dr. Hoobler's work in many respects shows better results than hitherto published. Very large doses of vaccine were used at comparatively frequent intervals. Dr. Hoobler's paper will be published in the August number of the *Archives of Pediatrics.*

132 West Eighty-first Street.

ABSTRACT OF DISCUSSION

DR. H. I. BOWDITCH, Boston: We ought to regret that Dr. Kerley's paper did not come earlier. I feel very strongly on the subject of the treatment with vaccines. I have had little personal experience, but in the clinics in Boston it is being used widely. In the Children's Hospital it is used in much smaller doses than Dr. Kerley mentions. There we are using Wright's method, from 1/50,000 of a milligram of "1.0" up to 1/20,000 of a milligram. This change in dose possibly is due to a different form of tuberculin that we use. It has been thought unwise to use it in local forms of tuberculosis. In glandular tuberculosis, so far as I have seen it used, it has given excellent results. The length of time required for the treatment is not determined. In six months one may hope to have some effect, but how much longer it must be employed to keep the process under control I do not know. Another point we are divided on is where surgical intervention comes in. Large glands which soften must be opened, but whether they should be curetted out and when the proper time for tuberculin arises, is not a settled question. Emptying the abscess with Wright's trocar seems to me the best method. The colon vaccine has been employed in pyelitis with varying success. Other vaccines, e. g., the staphylococcus, are not employed so often as they should be.

DR. J. P. SEDGWICK, Minneapolis: In my hospital service a few cases of typhoid were treated by vaccine therapy, and the results were so remarkable in one case that I intend to try it again this summer. There was a drop in the temperature curve, and I should like to know whether or not there is any connection between the result obtained and the treatment.

Dr. W. J. Butler, Chicago: Dr. Kerley's paper presents additional evidence of the advantages to be derived from vaccine and serum therapy in various infections. Staphylococcus and gonococcus infections have proved, in children, particularly amenable to vaccine therapy. I believe that I and my assistant, Dr. Long, were the first to demonstrate this for gonorrheal vulvovaginitis. While, in general, smaller doses of vaccine are employed in children, they tolerate large doses of the above vaccines without any marked general reaction. A local reaction at the site of injection, consisting of a slight induration that is somewhat tender, is usually observed, but is of no consequence. It is important, however, in an individual case to select a proper dose, and while there are in all probability other protective substances than opsonins produced following inoculations, an estimation of the latter forms the best guide at present in determining such dosage. There is probably no vaccine used in which an adherence to the latter is more important than in the use of tuberculin. I think that we owe a debt of gratitude to Dr. Flexner for placing in the hands of physicians throughout the country a specific serum for the treatment of epidemic cerebrospinal meningitis. I have used it in four cases, all of which, however, came under observation late in the disease, at a time when little could be hoped for from serotherapy, and all terminated fatally. In the experience of others, brilliant results have followed its early employment. I am not altogether convinced, however, that we have arrived at final conclusions as to how frequently it should be employed in a given case, especially in fulminating cases. The majority of statements on this point would seem to come from the clinical side and naturally are empirical.

A fuller knowledge of the active substances contained in the serum, the period of time in which such substances are exhausted when in contact with infected tissues, etc., might give us closer information of the frequency with which it should be used. A serum can possess, for instance, a definite antibody content, which, when brought in contact with the appropriate antigen, will be rapidly neutralized, become inactive, and consequently could not be of any further service. Kolle and Wassermann investigated the complement-binding amboceptor of antimeningococcus serum, which was, of course, first produced by Joachmann of Breslau. Joachmann must be recognized as its discoverer, in the same manner that we accord Bierring the credit for diphtheria antitoxin.

Kolle and Wassermann concluded that it contained a complement-binding antibody. It undoubtedly contains other protective substances.

MASSAGE IN GENERAL MEDICINE

JOHN K. MITCHELL, M.D.
Physician to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases
PHILADELPHIA

Massage is a systematic manipulation of the body for definite therapeutic ends. This manipulation depends for its success on the precise performance of certain clearly described and well-understood movements of the hands in the process. While these movements are in a general way always of the same sort, each of them is capable of modification to meet varying indications as one would vary the dose, the frequency of administration, or the strength of a drug. It is absolutely necessary for the operator to keep in mind when applying the treatment the particular end to be sought in the individual patient. The skilful manipulator scarcely ever rubs two persons alike.

The several movements used consist of various applications of rubbing, kneading, stretching and pinching of the muscles and other tissues.

You will see that this simple definition of what massage is tells by implication what massage is not. It is not magnetism, or personal electricity, or magic, or bone-setting, nor is it a panacea or cure-all for disease. It is applied, not by a flow of mysterious influence from one person to another, but by two hands directed by intelligence and applied with knowledge. It is a method of treatment aiming to produce certain definite ends, which should be prescribed by a physician as a medicine is; in fact, it is a medicine in any wide sense of that word which would not limit it to indicate something which comes out of a bottle in drops or teaspoonsful. There are indications for its use exactly as there are indications for the prescription of a laxative or a heart tonic. To get the best results the physician should know why he is ordering it, and the operator should know, too. The main thing, the thing to be always held in mind in prescribing or applying any remedy, is that we are seeking to produce certain particular effects in the individual case under treatment.

What effects can we produce with massage? Now, in the main, the mechanical results of massage are those of active exercise. We can by its direct influence alter the circulation of the blood and lymph as may be desirable, either slowing or hurrying their currents; can improve the tone and in some degree the bulk of muscles; affect the whole digestive system according to the method of application so that the activity of the peristaltic movements may be increased, the secretions aided, or, if need be, quieting and soothing effects produced. The superficial nerves can be directly reached, and the deeper-lying nerves and excretory organs also, somewhat less immediately. The chief difference between massage and active exercise is that we can not expect by any passive manipulation to add greatly to the quantity or power of the muscular system, while with active exercise properly directed this is almost indefinitely possible. The second and more important difference is that massage makes no demand on the voluntary nervous system, so that patients in whom for any reason it is desirable to avoid drawing on weak or irritable nervous centers may thus be exercised, in this way conserving nervous energy and economizing the expenditure of will-power.

The greatest value of the treatment is in diseases which are due to altered metabolism, and in which the powers of digestion, absorption or assimilation are at fault. It is this effect on nutritive processes which has made massage so successful in the treatment of certain nervous disorders, especially those bugbears of the general practitioner, hysteria and neurasthenia, in their infinite multiplicity of forms and symptoms. These troubles are caused in large part, so far as our present knowledge can tell us, by defects of assimilation or other disturbances of nutrition, and, as I have said, nutrition may be profoundly influenced by regular and continued massage. It is, indeed, an integral part of rest treatment, the only unalterable requirement. Without it rest treatment is scarcely possible, and we should be in constant difficulties in attempting the use of rest in this form were it not for the possibility of improving the appetite, the digestion, and the general metabolic conditions by means of massage.

The special forms of massage, light superficial rubbing, surface stimulation by vibratory movements and tapping, slightly deeper friction by finger-tip and open-hand pressure, and, more important, the manipulation by deep kneading, all have their influences, but the combination of these four basic movements, which make up what we call "general massage," have more effect than any of the individual movements used separately. This is obvious clinically from what one sees in the patient, and subjectively is to be learned from the patient's feelings, while physiologic experiment has proved very satisfactorily in a measured and precise fashion the immense influence of this "combined manipulation" on circulation and secretion.

Some of the movements and systems of massage in use are, in my opinion, either useless or deleterious. Certain operators perform a number of fantastic and airy movements which may influence the surrounding atmosphere, but can not much affect the patient. Indeed, these light tappings and slappings are excessively irritating to some sensitive and nervous patients and should, therefore, be restricted to those cases in which an effect of stimulation of a passing kind is desirable. The vital, useful, alterative movements are the deep ones.

When a patient is rubbed for an hour, which is about the average time that should be taken for the careful manipulation of an ordinary sized person in ordinary flesh, certain very obvious effects are produced. In the first place (if we take a patient, let us say, at the end of a week's manipulation when the early strangeness and possible disagreeableness of being handled and pulled about has passed), in a successful case we shall hear from the patient that the operation leaves him with a slight and not at all disagreeable sense of lassitude, scarcely to be called fatigue, usually with a moderate degree of drowsiness and a sense of pleasant well-being. If, like most neurasthenic subjects, he has "that tired feeling," this should be lessened by each treatment, a gentle warmth should be felt over the whole surface, a distinct sense of stimulation of the circulation, an increase of appetite, an improvement of digestion, both gastric and intestinal, and sounder and longer sleep. Physiologically speaking, there is a temporary slight increase of temperature in almost all cases, from half a degree to a degree Fahrenheit, usually. If the manipulation has been a slow and deep one, not unduly prolonged, the pulse will be slower and stronger afterward. Too long-continued manipulation, while at first followed by this improvement in the force and slowing of the speed of the pulse, may show a reaction of a less favorable kind afterward.

Superficial rubbing, especially if both superficial and rapid, will usually result in the pulse becoming quicker and weaker, so that if patients say that they can not stand massage because it leaves them irritated and with a discomforting sense of rapid heart action afterward, some inquiry should be made as to the method in which treatment is being carried out. Judging by my own very large experience, there must be very few patients who can not be rubbed.

There is an absolute increase, susceptible of measurement, in the flow of blood through any part. There is an enormous addition to the actual number of red blood cells in circulation, as I have proved by blood counts before and after treatment. It is probable that this is the result of the deep manipulation bringing into the circulation from the various tissues producing or storing up red blood a number of partially developed or transition cells and later to an actual stimulation of production of red cells. There is also a distinct addition to the quantity of intestinal and lymphatic secretion and the improved movement of the blood and lymphatic currents and nutrition in every direction throughout the system. One marked effect produced by this change in circulation is an increase in the amount of the urinary secretion, which is not only greater in quantity, but contains more than the normal solids during the hours succeeding treatment. The motor, sensory and trophic nerves are all stimulated in their several functions, the most direct evidence of which is the general improved vasomotor control.

One need not describe the effects on pathologic processes, as they may readily be inferred from these statements of the physiologic effects.

As concrete examples of the kind of cases in which massage will prove valuable, I briefly cite a few instances:

In simple anemia an increase of red blood cells can be demonstrated, amounting to from 15 to 50 per cent. This effect, at first temporary, lasts longer and longer as the massage is continued and with the establishment of improved nutrition becomes permanent.

In a case of extreme anemia in which the red cells were only 2,600,000 and the hemoglobin 56 per cent., the first massage increased the amount of the red cells to 4,600,000, without any increase in the hemoglobin. This first effect of manipulation was not maintained, the count in a few days dropping to 3,200,000 after massage.

In a case of chronic lead-poisoning with 4,000,000 corpuscles and only 30 per cent. of hemoglobin, the red cells were temporarily increased by massage to over 6,000,000. It could, of course, not be expected that so great an increase would be maintained and it was, indeed, abnormal, but this first effect greatly increased the comfort of the patient, and, although the increase was not kept up to this height, it did go on steadily. In a case of anemia so severe as to resemble the pernicious variety, but in which ultimate recovery ensued, the red cells went from 1,500,000, the percentage of hemoglobin being 18, to 1,650,000, with the first treatment. In a week the count was over 3,000,000 before massage and the percentage of hemoglobin was doubled, and after massage the cells rose temporarily to over 5,000,000.

Whether such results as these can be attained will depend altogether on the character and duration of the massage applications. Light rubbing, slapping and tickling will not produce the desired effects, but deep slow manipulations for fifty or sixty minutes will, and if these results do not follow massage it may be at once concluded that the massage is either not the right sort or not rightly used.

In chronic constipation, with careful, continued and frequently repeated massage of the intestines, the accumulations of the bowel may be emptied, the weakened intestinal muscles stimulated, the secretions—nearly always deficient in this disease—brought back in normal quantity, and, when patients have begun to improve, a careful and punctual habit of defecation may be inculcated and a permanent cure thus result. Before attempting to use massage for chronic constipation it is necessary to empty the bowels thoroughly by high enemas, lest there should be some retention of feces in the colon, which sometimes happens, even when the bowels are being moved reasonably well daily by means of purgatives. If abdominal massage is applied while these matted masses are present in the bowel, inflammatory disturbances might result.

In nervous diseases, to take a common example, chorea will be treated more successfully, so far as duration is concerned, and much more satisfactorily, so far as the permanence of the results go, by a short time in bed with very slow, quiet, deep kneading of the muscles than by any combination of drugs yet evolved.

In another disease of unknown pathology, but with its effects chiefly perceived in the muscles, paralysis agitans, results are attained which enormously increase the ease and comfort of the patient; the ache resulting from the constant overuse of the flexor muscles can be relieved and a degree of relaxation brought about attainable in no other way, and in favorable cases something really approaching a cure may be expected. Training in relaxation, extension movements, slow, full and sweeping, are added after a short course of massage, and the characteristic gait and carriage may also be improved by proper exercises.

In sprains, to select another disorder of a very different sort for an example, no treatment is so successful as early and frequently repeated massage. Sprains of the knee, ankle, elbow or wrist, may thus be treated from the very first day of their course, and, indeed, the earlier the treatment can be begun the briefer will the time of disablement be and the more completely successful the result.

The results of peritonitis, however caused, are excessively difficult and unsatisfactory to handle; if adhesions form, the impairment of the efficiency of the intestines and other abdominal organs may be very great. In one striking example of this we had the advantage of ocular demonstration. The late Professor Goodell attempted operation to relieve what seemed to be adhesions in the intestine. He opened the abdomen and found the whole abdominal contents so matted in one mass by old inflammations that no surgical interference was possible at all. Dr. Goodell closed the wound and in due time returned the patient to me for general treatment. Persistent massage during six months relieved the difficulty to such an extent that a woman who before had not had a stool without mechanical assistance in some years recovered excellent functional activity of the intestines and remained well for a number of years afterward, when I lost sight of her.

One might go on with a number of examples of possible uses of this form of treatment, but, not to elaborate them needlessly, I will add only one or two others.

In the first incompetence of a failing heart massage may be used successfully as an aid to circulation, thus lessening the work and consequent strain on the heart, as well as maintaining the condition of the patient.

In convalescence from acute disease, especially those of length and severity enough to cause considerable enfeeblement, this long-drawn period of invalidism may be greatly shortened and the patient much sooner placed on his feet by the use of massage in its general form.

It would perhaps be trespassing on the province of the surgeon if I called attention to the use of massage in hastening the healing in fracture cases.

Before closing, having thus in a very brief and hasty way outlined the value and importance of massage properly understood and legitimately applied, it may be worth while for me as a student for many years of the therapeutics of bodily exercises and of mechanical means of treatment to say something as to some illegitimate methods of use of a perfectly proper means. Odds and ends of physiologic and anatomic information, misty notions trickling through strata of ignorance as to the uses of manipulation, have resulted in the putting forward of some imperfect, half-understood and ill-applied forms of massage as cure-alls. For a time there was quite a run on a system called neurotherapy, which has now disappeared into the limbo of lost quackeries. This was massage badly done, and so for a year or two we heard of a good many serious injuries as a result of application in unsuitable cases. At the present moment the chief folly of the kind is osteopathy; the vehemence wherewith its advocates deny that it is massage causes the suspicion which is always natural when people "protest too much." I have read their books and seen their practice, and so far as can be gathered from the very nebulous statements of the inventor and of his followers there are two chief causes of disease. All those which affect the head, neck, chest, especially the pulmonary diseases, but including various serious diseases of the brain, croup and diphtheria (which Dr. Still considers one disease), bronchitis, and consumption are due to defects in the secretion, if you please, of cerumen in the ear! Nearly all other bodily troubles of any kind are due to dislocations or to fractures undiscoverable by the touch of a mere surgeon and invisible to the *x*-ray. If a patient is constipated, it is because some bones are pressing somewhere on the nerves or vessels supplying the intestines. Whooping-cough is due to the pressure of the hyoid bone on the pneumogastric nerve, together with deficiency in the quantity and quality of ear-wax.

Theoretically, besides the ear-wax difficulty (which is treated by the use of glycerin in the ear), these diseases are all to be cured by replacing the bones in their proper relations; practically, they are treated by severe, yes, ferocious, massage. The feelings of the osteopath are, as I have said, hurt when one calls his manipulations massage; it *is* rather hard on massage.

If it were not for that extraordinary affection with which the American citizen at large regards a quack, one would scarcely have to give so much time and consideration to a system which finds the same causes bring about whooping-cough, apoplexy, smallpox, dyspepsia and heart disease.

The real fact is that if massage were properly understood and properly appreciated as an invaluable medical aid the osteopaths would never had the success which has attended them. If there is any one thing certain from a study of their methods, it is that they have found out and made use of the immense value of massage and manipulation, and, as a result, are teaching, without perhaps intending to do so, the important lesson to the public of the value and necessity of bodily exercise, but that they do so in such a manner as to cause frequent damage and almost constant danger is another matter. The most serious accusation against them is that they claim to do impossible things, and in attempting them do dangerous things.

1730 Spruce Street.

INTESTINAL AUTOINTOXICATION AS A FACTOR IN THE CAUSATION OF PATHOLOGIC CONDITIONS OF THE EAR, NOSE AND THROAT *

J. A. STUCKY, M.D.
LEXINGTON, KY.

Further observations, confirmed by clinical and laboratory data since publication of my papers on this and kindred topics in 1902, 1904 and 1906, serve only to establish more firmly the views then expressed. The question of intestinal autointoxication, toxemia and lithemia, has at last come to the front where it belongs, and has gained wide attention from the medical profession both in Europe and America, and the results and treatment of putrefaction and toxemia originating in the intestinal canal have become matters of great importance not only to the general practician, but to the otorhinologist. Unsatisfactory results obtained after months of surgical and local treatment of some diseases of the ear, nose and throat have stimulated a more careful search for reasons why permanent relief was so rarely obtained from usual accepted and time-honored methods of treatment.

---

* Read at the Meeting of the American Rhinological, Laryngological and Otological Society, Atlantic City, June 2-3, 1909.

The question of normal and abnormal nasal respiration has been settled long ago—but the correction of these did not relieve or restore many to the normal condition, and careful investigation reveals the fact that the systemic conditions has as much to do with a large percentage of cases as does the local condition, or more.

We know that when the middle ear and nasal accessory sinuses suffer from "air hunger" as a result of imperfect or obstructed drainage and ventilation they do not functionate normally, and discomfort and pathologic conditions follow. Retained secretions become purulent and lead to sepsis and various functional disturbances, gastric, neurotic, circulatory and mental.

"Evidences from histology, comparative anatomy, experiments on animals and clinical observation show that the nose is the organ through which the current of air should pass in normal breathing; also that lowered vitality, accompanied by a variety of general symptoms, is often due to nasal obstruction." It is no less true that these conditions are caused by the systemic disturbance, a frequently overlooked factor.

For instance, there are more causes for deafness than (1) interference with the passage of sound to the terminal filaments of the auditory nerve, and (2) interference with the transmission of sound from the terminal filaments to the brain. We may have fatigue—a state of weakness, suspension of or inability to transmit its special stimulus or to interpret that stimulus correctly. As, in the eye, we may have an asthenopia or weakness of vision, so we may have a similar condition in the ear. We may have a functional disturbance due neither to internal or middle-ear disease. Occasionally we meet cases, the symptoms of which would indicate middle-ear disease; in another group the symptoms indicate disease of the internal ear, yet careful examination reveals that neither disease exists; hence we must look elsewhere for the cause. There is a middle class due to systemic disturbances. Since in the eye we may have diminished or obliteration of function from toxemia, why may we not for the same reason have a similar condition in the ear? That we do meet toxemia of the auditory apparatus I have frequently demonstrated. In this class of cases we find some disorder of the nervous, digestive, excretory or circulatory system which has intensified a comparatively trivial irregularity of the ear into troublesome deafness.

Richard Lake says: The great diagnostic feature of this class of cases is an excessive loss of bone conduction (C mastoid) compared with the high degree of hearing power, as tested by the conversational voice, acoumeter and whisper. There is also in most instances a marked loss of ærial conduction, as tested by a wide range of tuning-forks, and frequently musical tones and sounds are less adversely affected than noises.

Labyrinthine hyperemia is often caused by alcohol, overeating, gout, rheumatism and certain drugs, as quinin, ether and salicin. A large causative influence is also exerted in this condition by hyperplasia of the labyrinthine capsule and certain systemic conditions (i. e., lithemia and gout), due to a toxemia which I have demonstrated to be of intestinal origin.

In cases of interference with motion and fixation of the sound-conducting chain, if the real seat of the pathologic condition is the bony capsule of the labyrinth, what is the cause of this condition? Also if lithemia, gout and rheumatism may produce ankylosis or interference with functions of one part of the body, why not in another part?

Undoubtedly as the result of many years of disturbed function organic changes may take place in the intratympanic structures which are incapable of resolution, and many persons would escape the annoyance of tinnitus and humiliation of deafness, if preventive surgery had been used and proper living practiced.

I am fully in accord with views of Bezold, Siebenmann, Tweedie, Lake and many of our American otologists, that there can be no doubt that the general constitution of the patient furnishes the main basis for the etiology of otosclerosis, and that it can not be attributed to a local harmful influence affecting the ear exclusively.

In several hundreds of cases of diseases of the nasal accessory sinuses, middle and internal ear in which surgical interference was not indicated, and in all in which it was indicated and operative procedure resorted to, I have found unmistakable and marked evidence of toxemia of intestinal origin as evidenced by excessive quantity of indican in the urine, and when the condition causing this was removed there was marked amelioration or entire relief of the disease.

I do not believe that every functional disease has a structural derangement to account for it. No mechanism is sufficient for function simply because it is a mechanism. Each must have its special power for successful operation, and the source of power is in the blood. That the blood is poisoned through absorption of toxic material from the intestinal canal more frequently than from any other source I think will not be questioned. Food and drugs, once in the circulation, select the nervous function which they specifically arrange or derange, and some functional changes produce organic changes due to possession of chemical affinities, alcohol producing structural changes in the kidney and sclerotic changes in nerve and liver tissue. Functional diseases are usually intermittent; a broken or destroyed nerve fiber stays broken. Gouty poisons must accumulate in the blood a long while before the attack of gout. There may be a sudden explosion of uremia, but the blood has been uremic for some time before. I have seen gastrointestinal disorders severe enough to destroy life, which yet left no evidence of inflammatory elements. The neurologists tell of severe cases of melancholia due to fecal accumulation. The general law of nervous organization is that a repeated excitation of the nerve center will, in time, anatomically modify that center. If this law be true in one instance, why not true in another? We know that contraction of the circulation, resulting in hyperemia or ischemia with venous stasis, is sometimes brought about by the condition known as lithemia. (This term was first used by the late Dr. J. M. DaCosta, who described it as American gout, analogous to the uric acid diathesis, there being, however, no uric acid present, the irritation being some other chemical substance, perhaps alkaline instead of acid.) Quinin and salicylates cause the tinnitus, probably, by producing hyperemia of the labyrinth, as they increase the blood tension until actual toxic effects are manifested, when the tension is reduced. I have frequently seen the same conditions, the result of imperfect nutrition or overnutrition and defective elimination. Toxins, owing to disturbed body chemistry, are manufactured daily in the intestinal canal and remain in the system; the result is a protest from the irritated nerves and poisoned cells, manifested in rheumatic pains, asthmatic attacks, vertigo, obscure neuroses of eye, ear, nose and throat, neuralgias and periodic headaches; all these being evidence of systemic poisoning. This poison I have almost invariably found to be indican in the urine.

no other way, and in favorable cases something really approaching a cure may be expected. Training in relaxation, extension movements, slow, full and sweeping, are added after a short course of massage, and the characteristic gait and carriage may also be improved by proper exercises.

In sprains, to select another disorder of a very different sort for an example, no treatment is so successful as early and frequently repeated massage. Sprains of the knee, ankle, elbow or wrist, may thus be treated from the very first day of their course, and, indeed, the earlier the treatment can be begun the briefer will the time of disablement be and the more completely successful the result.

The results of peritonitis, however caused, are excessively difficult and unsatisfactory to handle; if adhesions form, the impairment of the efficiency of the intestines and other abdominal organs may be very great. In one striking example of this we had the advantage of ocular demonstration. The late Professor Goodell attempted operation to relieve what seemed to be adhesions in the intestine. He opened the abdomen and found the whole abdominal contents so matted in one mass by old inflammations that no surgical interference was possible at all. Dr. Goodell closed the wound and in due time returned the patient to me for general treatment. Persistent massage during six months relieved the difficulty to such an extent that a woman who before had not had a stool without mechanical assistance in some years recovered excellent functional activity of the intestines and remained well for a number of years afterward, when I lost sight of her.

One might go on with a number of examples of possible uses of this form of treatment, but, not to elaborate them needlessly, I will add only one or two others.

In the first incompetence of a failing heart massage may be used successfully as an aid to circulation, thus lessening the work and consequent strain on the heart, as well as maintaining the condition of the patient.

In convalescence from acute disease, especially those of length and severity enough to cause considerable enfeeblement, this long-drawn period of invalidism may be greatly shortened and the patient much sooner placed on his feet by the use of massage in its general form.

It would perhaps be trespassing on the province of the surgeon if I called attention to the use of massage in hastening the healing in fracture cases.

Before closing, having thus in a very brief and hasty way outlined the value and importance of massage properly understood and legitimately applied, it may be worth while for me as a student for many years of the therapeutics of bodily exercises and of mechanical means of treatment to say something as to some illegitimate methods of use of a perfectly proper means. Odds and ends of physiologic and anatomic information, misty notions trickling through strata of ignorance as to the uses of manipulation, have resulted in the putting forward of some imperfect, half-understood and ill-applied forms of massage as cure-alls. For a time there was quite a run on a system called neurotherapy, which has now disappeared into the limbo of lost quackeries. This was massage badly done, and so for a year or two we heard of a good many serious injuries as a result of application in unsuitable cases. At the present moment the chief folly of the kind is osteopathy; the vehemence wherewith its advocates deny that it is massage causes the suspicion which is always natural when people "protest too much." I have read their books and seen their practice, and so far as can be gathered from the very nebulous statements of the inventor and of his followers there are two chief causes of disease. All those which affect the head, neck, chest, especially the pulmonary diseases, but including various serious diseases of the brain, croup and diphtheria (which Dr. Still considers one disease), bronchitis, and consumption are due to defects in the secretion, if you please, of cerumen in the ear! Nearly all other bodily troubles of any kind are due to dislocations or to fractures undiscoverable by the touch of a mere surgeon and invisible to the *x*-ray. If a patient is constipated, it is because some bones are pressing somewhere on the nerves or vessels supplying the intestines. Whooping-cough is due to the pressure of the hyoid bone on the pneumogastric nerve, together with deficiency in the quantity and quality of ear-wax.

Theoretically, besides the ear-wax difficulty (which is treated by the use of glycerin in the ear), these diseases are all to be cured by replacing the bones in their proper relations; practically, they are treated by severe, yes, ferocious, massage. The feelings of the osteopath are, as I have said, hurt when one calls his manipulations massage; it *is* rather hard on massage.

If it were not for that extraordinary affection with which the American citizen at large regards a quack, one would scarcely have to give so much time and consideration to a system which finds the same causes bring about whooping-cough, apoplexy, smallpox, dyspepsia and heart disease.

The real fact is that if massage were properly understood and properly appreciated as an invaluable medical aid the osteopaths would never had the success which has attended them. If there is any one thing certain from a study of their methods, it is that they have found out and made use of the immense value of massage and manipulation, and, as a result, are teaching, without perhaps intending to do so, the important lesson to the public of the value and necessity of bodily exercise, but that they do so in such a manner as to cause frequent damage and almost constant danger is another matter. The most serious accusation against them is that they claim to do impossible things, and in attempting them do dangerous things.

INTESTINAL AUTOINTOXICATION AS A FACTOR IN THE CAUSATION OF PATHOLOGIC CONDITIONS OF THE EAR, NOSE AND THROAT *

J. A. STUCKY, M.D.
LEXINGTON, KY.

Further observations, confirmed by clinical and laboratory data since publication of my papers on this and kindred topics in 1902, 1904 and 1906, serve only to establish more firmly the views then expressed. The question of intestinal autointoxication, toxemia and lithemia, has at last come to the front where it belongs, and has gained wide attention from the medical profession both in Europe and America, and the results and treatment of putrefaction and toxemia originating in the intestinal canal have become matters of great importance not only to the general practician, but to the oto-rhinologist. Unsatisfactory results obtained after months of surgical and local treatment of some diseases of the ear, nose and throat have stimulated a more careful search for reasons why permanent relief was so rarely obtained from usual accepted and time-honored methods of treatment.

---

*Read at the Meeting of the American Rhinological, Laryngological and Otological Society, Atlantic City, June 2-3, 1909.

The question of normal and abnormal nasal respiration has been settled long ago—but the correction of these did not relieve or restore many to the normal condition, and careful investigation reveals the fact that the systemic conditions has as much to do with a large percentage of cases as does the local condition, or more.

We know that when the middle ear and nasal accessory sinuses suffer from "air hunger" as a result of imperfect or obstructed drainage and ventilation they do not functionate normally, and discomfort and pathologic conditions follow. Retained secretions become purulent and lead to sepsis and various functional disturbances, gastric, neurotic, circulatory and mental.

"Evidences from histology, comparative anatomy, experiments on animals and clinical observation show that the nose is the organ through which the current of air should pass in normal breathing; also that lowered vitality, accompanied by a variety of general symptoms, is often due to nasal obstruction." It is no less true that these conditions are caused by the systemic disturbance, a frequently overlooked factor.

For instance, there are more causes for deafness than (1) interference with the passage of sound to the terminal filaments of the auditory nerve, and (2) interference with the transmission of sound from the terminal filaments to the brain. We may have fatigue—a state of weakness, suspension of or inability to transmit its special stimulus or to interpret that stimulus correctly. As, in the eye, we may have an asthenopia or weakness of vision, so we may have a similar condition in the ear. We may have a functional disturbance due neither to internal or middle-ear disease. Occasionally we meet cases, the symptoms of which would indicate middle-ear disease; in another group the symptoms indicate disease of the internal ear, yet careful examination reveals that neither disease exists; hence we must look elsewhere for the cause. There is a middle class due to systemic disturbances. Since in the eye we may have diminished or obliteration of function from toxemia, why may we not for the same reason have a similar condition in the ear? That we do meet toxemia of the auditory apparatus I have frequently demonstrated. In this class of cases we find some disorder of the nervous, digestive, excretory or circulatory system which has intensified a comparatively trivial irregularity of the ear into troublesome deafness.

> Richard Lake says: The great diagnostic feature of this class of cases is an excessive loss of bone conduction (C mastoid) compared with the high degree of hearing power, as tested by the conversational voice, acoumeter and whisper. There is also in most instances a marked loss of ærial conduction, as tested by a wide range of tuning-forks, and frequently musical tones and sounds are less adversely affected than noises.

Labyrinthine hyperemia is often caused by alcohol, overeating, gout, rheumatism and certain drugs, as quinin, ether and salicin. A large causative influence is also exerted in this condition by hyperplasia of the labyrinthine capsule and certain systemic conditions (i. e., lithemia and gout), due to a toxemia which I have demonstrated to be of intestinal origin.

In cases of interference with motion and fixation of the sound-conducting chain, if the real seat of the pathologic condition is the bony capsule of the labyrinth, what is the cause of this condition? Also if lithemia, gout and rheumatism may produce ankylosis or interference with functions of one part of the body, why not in another part?

Undoubtedly as the result of many years of disturbed function organic changes may take place in the intratympanic structures which are incapable of resolution, and many persons would escape the annoyance of tinnitus and humiliation of deafness, if preventive surgery had been used and proper living practiced.

I am fully in accord with views of Bezold, Siebenmann, Tweedie, Lake and many of our American otologists, that there can be no doubt that the general constitution of the patient furnishes the main basis for the etiology of otosclerosis, and that it can not be attributed to a local harmful influence affecting the ear exclusively.

In several hundreds of cases of diseases of the nasal accessory sinuses, middle and internal ear in which surgical interference was not indicated, and in all in which it was indicated and operative procedure resorted to, I have found unmistakable and marked evidence of toxemia of intestinal origin as evidenced by excessive quantity of indican in the urine, and when the condition causing this was removed there was marked amelioration or entire relief of the disease.

I do not believe that every functional disease has a structural derangement to account for it. No mechanism is sufficient for function simply because it is a mechanism. Each must have its special power for successful operation, and the source of power is in the blood. That the blood is poisoned through absorption of toxic material from the intestinal canal more frequently than from any other source I think will not be questioned. Food and drugs, once in the circulation, select the nervous function which they specifically arrange or derange, and some functional changes produce organic changes due to possession of chemical affinities, alcohol producing structural changes in the kidney and sclerotic changes in nerve and liver tissue. Functional diseases are usually intermittent; a broken or destroyed nerve fiber stays broken. Gouty poisons must accumulate in the blood a long while before the attack of gout. There may be a sudden explosion of uremia, but the blood has been uremic for some time before. I have seen gastrointestinal disorders severe enough to destroy life, which yet left no evidence of inflammatory elements. The neurologists tell of severe cases of melancholia due to fecal accumulation. The general law of nervous organization is that a repeated excitation of the nerve center will, in time, anatomically modify that center. If this law be true in one instance, why not true in another? We know that contraction of the circulation, resulting in hyperemia or ischemia with venous stasis, is sometimes brought about by the condition known as lithemia. (This term was first used by the late Dr. J. M. DaCosta, who described it as American gout, analogous to the uric acid diathesis, there being, however, no uric acid present, the irritation being some other chemical substance, perhaps alkaline instead of acid.) Quinin and salicylates cause the tinnitus, probably, by producing hyperemia of the labyrinth, as they increase the blood tension until actual toxic effects are manifested, when the tension is reduced. I have frequently seen the same conditions, the result of imperfect nutrition or overnutrition and defective elimination. Toxins, owing to disturbed body chemistry, are manufactured daily in the intestinal canal and remain in the system; the result is a protest from the irritated nerves and poisoned cells, manifested in rheumatic pains, asthmatic attacks, vertigo, obscure neuroses of eye, ear, nose and throat, neuralgias and periodic headaches; all these being evidence of systemic poisoning. This poison I have almost invariably found to be indican in the urine.

Greene M. Hammond, writing on neuritis from autointoxication, says that, while the presence of indican in the urine is significant of this condition, he does not consider indol alone a very toxic agent, but looks on skatol and butyric acid as much more powerful toxins.

Metchnikoff[1] concludes that in the putrefactive bacilli in our digestive canal we have a source of autointoxication against which the organization has to fight with all the means at its command. The intestinal putrefaction corresponds simply to the first appearance of putrefaction outside of the living organism.

Fermentation of carbohydrates occurs in the lower ileum and colon; putrefaction of proteids takes place in the large intestines. Putrefaction, except in the pathologic condition, never occurs above the iliocecal valve.

Herter found that administration of indol to healthy individuals caused frontal headaches, irritability, insomnia, and confusion; a long continuance of absorption of indol caused a strong reaction for indican in the urine sufficient to cause neurasthenic symptoms. Gases and other products of fermentation are mostly absorbed by the intestinal wall.

Ortiveiler and Muller say that the amount of indican in urine varies with the length of time the feces remain in the colon, with the activity of peristalsis, and with the site of putrefaction of proteins; when putrefaction extends up into the small intestine, urine indican is much increased.

Hammond's remarks as to the influence of diet are so important that I quote:

> It is commonly believed that proteid foods are the ones concerned in the formation of putrefactive toxins; that is in the main, true, but it is quite clear to me that all forms of food, when eaten in greater quantities than the digestive fluids can digest, are capable of forming putrefactive poisons, which are deleterious to the human organisms. I have, therefore, insisted that all my patients should eat small meals in which the proteid foods should form a very small proportion. To my mind it is not so much what the patient eats, as how he eats. I have found the best results follow when general food was given, but the quantity of food of any kind was limited *to a very small amount. Most people habitually eat, at least* once a day and frequently at all meals, not only much more food than they need, but much more than they can digest. In the latter case putrefactive decomposition naturally follows. This may be obviated by giving only as much food as can be digested, and it is even better to give, for a time at least, even less than this amount. When this plan was followed every day for a number of days, the putrefactive products in the urine were invariably decreased and in some cases entirely disappeared.

In this paper I have attempted to emphasize briefly, as suggested by the title, the importance of intestinal autointoxication as a factor in the causation of pathologic conditions of the ear, nose and throat. In a subsequent paper I shall mention somewhat in detail the specific manifestations of these pathologic conditions; the treatment employed and results obtained.

Forest Highlands for Sanatoriums.—The Committee of One Hundred on National Health suggests that some of the great lumber companies could allow some of their large tracts of forest lands situated high in the mountains to be used for tuberculosis sanatoriums. As a reciprocal arrangement it is suggested that the state could remit taxes on the lands which lumber companies lease for sanatorium purposes. The tenure would be temporary and under conditions agreeable to all concerned. A further suggestion is made that life-insurance companies could undertake the management and that railroads could aid greatly by making reduced rates at appropriate intervals for the transportation of tuberculosis sufferers.

Clinical Notes

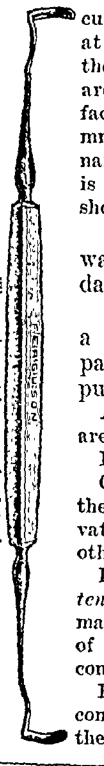
A NEW METHOD FOR DETACHING THE CATARACT IN ITS CAPSULE

G. C. SAVAGE, M.D.

NASHVILLE, TENN.

I wish to say a word—probably not the last word—on the extraction of cataract in its capsule. Of the Smith operation, which in recent years has attracted the attention of the world, all that need be said has been told by Greene[1] in The Journal. In the same issue Würdemann advocates the operation, but gives credit to Pagenstecher. Major Smith,[2] in The Journal of September 11, shows clearly that Pagenstecher himself makes no such claim, but, on the contrary, gives credit to Smith. Smith quotes Pagenstecher as calling Smith's "the best operation in the world; I will do nothing else."

While Greene was reading his paper I saw more clearly than ever the amount of trauma necessary in the Smith operation, and became more convinced that this particular operation could never become universal. He had not finished his paper until I had drawn, on the margin of my copy of the program, an instrument for detaching the cataract in its capsule. I later found that my first conception of this instrument was perfect. On my arrival in Philadelphia, from Atlantic City, I arranged for the making of a model. This I brought home with me for trial on pigs' eyes. It proved so satisfactory on these eyes, also on a human eye which had been enucleated, that I returned it to the manufacturer with the request that he make me three detachers just like the original model, differing only in the length of the curves. The following description will be more easily understood in the light of the accompanying illustration:



The cataract-in-capsule detacher.

> The instrument terminates at each end in a double curve, the one in line with the handle and the other at right angles to this line. The point of bending is the point of union of the two curves. The two curves are to have the same radius as has the anterior surface of the lens, and the curves are to be 5, 6 and 7 mm. long, for the reason that eyes vary in size. The name will be the "cataract-in-capsule detacher." It is a right- and left-handed instrument, as the cut shows.

The model was made on June 12, 1909, and was used on animal eyes for the first time two days later, June 14.

The means described above makes necessary a new method of operation—new in essential particulars. The following is the method to be pursued:

A. Patient, instruments, operator and assistant are to be thoroughly prepared.

B. Complete local anesthesia is to be used.

C. Lids are to be separated by a stop-speculum, or the upper lid held up by the assistant, with lid elevator, while the lower lid is pulled down by the other hand of the assistant.

D. The operator fixes the eyeball by *grasping the tendon of the internus;* then with the other hand he makes the corneal incision of the usual size (5/11 of the circumference), associating with it a good conjunctival flap.

E. If an iridectomy is to be done, the one hand continues to fix the globe, while with his other hand the operator seizes the iris with iris forceps and gently draws it out through the incision just far enough to enable an assistant to make a vertical snip of the iris with iris scissors, close to the tip of the forceps. The ideal operation, however, is without iridectomy.

---

[1] Greene, D. W.: Experience in Expression of Cataract in Capsule by Smith Method, The Journal A. M. A., Sept. 4, 1909, liii, 777.

[2] Smith, Henry: The Smith Operation for Cataract, The Journal A. M. A., Sept. 11, 1909, liii, 882.

F. The iridectomy having been done—or if the iridectomy is not to be done—the operator, still continuing to fix the eye with his grasp of the tendon, takes in his other hand the cataract-in-capsule detacher and, passing it into the anterior chamber, he directs the free point of the horizontal curve between the iris and anterior capsule, pressing it gently downward until both the horizontal and vertical curves are behind the iris, or between the iris and the cataract; and now the detacher is to be so held that the horizontal curve shall rest on the lens below, but parallel with, the horizontal meridian of the lens, while the vertical curve shall rest on the lens to the outer side of, but parallel with, the vertical meridian of the lens, half way between the center and the margin. This is the primary position of the detacher.

On two movements of the detacher depends the success of the operation:

1. The vertical curve is made to press against the lens in such a way as to rotate it on its vertical axis, causing the outer margin of the cataract to move backward while the inner margin is made to advance to the same extent. The effect of this movement of the detacher is to tear loose the ligament laterally, the tear including much more than two quadrants, leaving untorn, probably, only a few fibers directly above and below. Now the instrument must be returned to the primary position, thus replacing the cataract in its normal position.

2. The horizontal curve of the detacher must now be made to rotate the cataract on its transverse axis by advancing the free end of the instrument while making *gentle* pressure against the cataract below its center. The effect is to make the lower margin of the cataract recede while the upper margin advances accordingly. This motion tears loose the few remaining fibers of the ligament, above and below, making easy the next step.

3. The cataract in its capsule having been torn loose by the two movements of the detacher outlined in 1 and 2 above, this instrument should be withdrawn from the eye, and the cataract in the capsule should be delivered by external pressure, in the old-time way, often without any counter-pressure, the globe still being held by means of the tendon-grasp. Occasionally light external pressure will show that some of the ligaments remain intact, as in one of my eight cases. In such a case the fixation forceps should be laid aside that the left hand may make counter-pressure with the shank of the cystotome until the cataract in the capsule presents in the corneal incision. At this moment the counter-pressure should cease and the presenting cataract should be transfixed from behind with the point of the cystotome, by means of which the cataract may be lifted out, thus minimizing the amount of further external pressure on the lower part of the cornea.

By this method of continued fixation, detaching and delivering, the operation is simple, easy and safe, and the trauma is very slight. Subsequent irritation was practically nil in all of my eight cases.

This operation has been done twice by Dr. M. M. Cullum, one of my local confreres. After his first operation he turned to me and said: "Why, this operation is as easy as the old-time operation." After his second operation he telephoned me as follows: "Your operation beats the Smith operation a long way."

The after-treatment is the simplest, varying from the usual in that I leave the eye open behind a gauze flap after the second day.

What is new in this operation can be recognized easily by the reader, but I will summarize the points: (1) Method of fixation; (2) the detacher and the method of using it; (3) the transfixing of the lens from behind in cases requiring much external pressure.

The free use of pigs' eyes will give courage and confidence to the one about to adopt my operation.

137 Eighth Avenue North.

COMPLEMENT FIXATION WITH LECITHIN AS ANTIGEN IN PELLAGRA

A PRELIMINARY NOTE

C. C. BASS, M.D.
NEW ORLEANS

The original Wassermann reaction and its many modifications, though at first thought to be specific for syphilis, has been found in a number of other diseases that are all known, or thought, to be of protozoan origin. The reaction seems, then, to be limited to protozoan diseases with the exception of a few cases of advanced tuberculosis and leprosy.

The generally accepted theory of the etiology of pellagra the world over is that it is poisoning from eating improperly cured or diseased corn products. Lombroso extracted from spoiled corn an oil and other extractives with which he produced experimentally in animals a disease very similar to, or identical with, pellagra. In Italy, where there is much pellagra, the authorities have reduced the amount of the disease to less than one-fourth of what it was when the regulation against the use of diseased corn was begun. The work has been based on the maize theory. It should be remarked incidentally, however, that many of the cases have been isolated by providing a number of hospitals for the treatment of pellagra.

There are a few students, however, among whom may be mentioned Sir Patrick Manson, who dispute the maize theory, and believe the disease to be due to protozoa and cite as evidence the similarity of course, symptoms and pathology of the disease to syphilis and sleeping sickness.

In the research laboratory of Tulane Medical College we have so far tested the serum in six cases and all gave positive reactions. The technic followed was the original Wassermann, except that lecithin was used for antigen instead of syphilitic liver extract. The hemolytic system used was sheep corpuscles; serum of sensitized rabbits inactivated at 56° C for 30 minutes; and guinea-pig serum for complement. The patient's serum was inactivated before being tested. All six cases gave strong positive reactions. All the patients gave negative histories for syphilis; three were the mothers and one was the father of healthy children. One of the tests was made on blood taken twenty-four hours after death and is, therefore, not very reliable. One patient denied eating corn meal, though the diagnosis of pellagra appeared fully justified.

I fully recognize that these few positive Wassermann reactions in pellagra may be merely a coincidence and do not justify any conclusions, but if the observation is confirmed in a larger series it would tend to strengthen the idea that the disease may be of protozoan origin. It might also be of service in the diagnosis of the very many early or mild cases.

Still further, it would add another disease to the list for consideration in interpreting a positive Wassermann reaction.

741 Carondelet Street.

Mental and Physical Education.—The whole conception of the purpose and curriculum of a college education needs revision and into it must come a better relation of the physical with the mental life of the undergraduates. This characteristic feature of our educational system should furnish quiet years for thought and visions but it should, and that was the purpose of many of those who endowed them, make distinctly for efficient citizenship.—P. C. Phillips, in *Hygiene and Physical Education.*

COLIC IN AN INFANT DUE TO ADENOID HYPERTROPHY

C. C. WALLIN, M.D.
LEWISTOWN, MONT.

On reading Dr. Freeman's article entitled "Adenoid Hypertrophy During the First Year of Life and Its Treatment," I am constrained to report the following case. I well recall Dr. Morse's paper of two years ago, but neither in it nor in any other discussions of conditions induced by the hypertrophied adenoid have I seen attention called to the symptoms herein reported.

The case is that of a child about six weeks old, perfectly healthy and nursed by its mother, who was also in good condition. I was called one evening to see the infant—which I had delivered—on account of an attack of "wind colic." An enema brought relief, but the condition recurred the next day. The child was plainly a mouth breather, and according to the mother had difficulty in nursing as well as frequent attacks of colic. Examination with the little finger revealed a nasopharynx pretty well filled with adenoid growth. The child was placed on a small table, the father steadied the head while with an ordinary tongue depressor, the lower jaw was depressed and the smallest Beckman curette inserted. It was but the work of a moment to clean out the growth, and from that time on the child has had no colic.

In this instance the colic was due simply to the fact that, in its efforts to nurse, the child swallowed quantities of air. This is shown by the utter absence of any other symptoms of digestive disturbance and by the result of the operation.

As to the prevalence of hypertrophied adenoids in infants, I am convinced that it is far greater than usually recognized. An infant with normal air passages will keep its mouth closed, and "snuffles" and "catarrh" are more often due to adenoid hypertrophy than to syphilis or to any other condition. Neither "snuffles" nor "catarrh" invariably accompany even a decided overgrowth of the adenoid.

I am further convinced that it is rarely necessary to administer an anesthetic for the removal of adenoids in a child under a year old; indeed, I believe such a course is rarely justifiable.

Reconstruction of Bile Ducts.—Dr. Alfred H. Movius, Jamestown, N. D., writes that Dr. Arthur G. Sullivan's article on this subject in The Journal, Sept. 4, 1909, p. 774, suggests to him that a recent case, in which he did a partial reconstruction of the common duct, might be worth reporting. It is as follows: Patient: A Norwegian woman, aged 82, who had suffered with gall-stone colic for twenty years, came under observation in June, 1908. The skin over the entire body was decidedly jaundiced; more or less jaundice had been present for the past three months. The stools were clay-colored; the urine loaded with bile. A diagnosis of cholelithiasis with stone in common duct was made. *Operation:* The usual incision was made in the right hypochondrium. The gall-bladder was found to be atrophied and full of stones. After loosening the extensive adhesions, the gall-bladder was removed. The common duct was next opened and the stone removed. The lumen of the common duct, below the location of the stone, was very much contracted. Fearing occlusion of this portion of the duct and consequent poor drainage, Dr. Movius inserted a piece of rubber tubing 3/16 inch in diameter. The tube extended from ¼ inch above the incision in the common duct to ⅓ inch into the duodenum. The duct was then sutured with No. 1 chromicized catgut, one stitch passing through the rubber tube to hold it in place. The abdominal wound was closed in the usual way. Postoperative History: Drainage was left in for four days, after which time it was removed and wound allowed to heal. Healing was complete in eight days. The bowels showed active bile drainage within the first thirty-six hours and the urine contained very little bile. The rubber tube passed on the fourteenth day following operation. The patient left the hospital at the end of the fourth week.

Therapeutics

CARE OF THE MOUTH

Dr. S. Blair Luckie, of Chester, Pa. (*Dietetic and Hygienic Gazette*, June, 1909), says so many pertinent things in regard to the proper care of the mouth preventing disease that it is well to review his article. The mouth seems to be splendidly arranged for the propagation and even protection of bacteria. There are cavities, caverns, and crypts, not easily cleansed, which are moist and warm, and more or less food is deposited near or in these spaces, which forms suitable pabulum for the growth of bacteria. A disturbance of the general health may change the mucous and salivary secretions and may impair the health of the mucous membrane of the mouth. Digestive disturbances not only coat the tongue, but interfere with the health of the rest of the mouth. Decayed teeth or painful roots of the teeth cause the patient to avoid that side of the mouth in masticating. One or all of these conditions may be present and allow the growth and propagation of pathologic bacteria in the mouth. In fact, there is hardly a general disturbance that does not interfere with the normal health of the mouth, which means good teeth; clean, pink mucous membranes; normal saliva; good digestion; and sweet breath. When one remembers how generally the breath of an individual is not sweet; how generally the tongue is not clean; how generally there is some tooth or teeth abnormality in a patient; and how incompletely most patients cleanse their mouths and teeth, we should not be astonished to learn that not only are harmless bacteria more or less constantly present in the mouth, but that pathologic bacteria occurring in the mouth are the cause of many serious diseases.

Unfortunately, an individual does not always realize that his mouth is dirty. Before he notices it there has to be considerable inflammation, considerable disturbance of secretions, and a bad taste in his mouth. Luckie quotes Miller as stating that one unclean mouth harbors 1,140,000,000 bacteria that may be cultivated, many of which are pathogenic. It has been shown that some of these pathogenic bacteria may cause not only intestinal indigestion and putrefaction, but may even be a source of pernicious anemia. A healthy gastric juice kills most of these germs that are swallowed, but anything that interferes with the normal amount of hydrochloric acid in the stomach may allow these germs to be carried into the intestines unharmed, where they can continue to grow. Besides the septic bacteria, the pneumococcus, the bacillus of diphtheria, and the bacillus of tuberculosis are sometimes found in the mouth.

The frequency of alveolitis and gingivitis after forty, even in otherwise normal individuals, shows neglect in the care of the mouth.

These bacteria, harmless or harmful, which are present in the mouth, may be inhaled, may be swallowed, may be chewed into the food, may be sprayed during sneezing or coughing, and may be offered gratuitously to friends who are kissed.

The object of this article is to cause the physician, whenever he is consulted by any patient, to examine the mouth carefully, and to give careful advice for daily continued cleanliness; the character of the solutions he deems advisable to order, depending on the condition in which he finds the mouth. He should also urge the patient to consult his dentist immediately if there is any cleaning or filling of the teeth needed. He should also instruct mothers in the care of their children's mouths.

Medical inspectors and teachers in schools should not only see that the eyes and ears of the children are normal, and that acute infection is not in evidence, but should also examine the mouths and teeth of the children.

The normal bilateral chewing of food of normal toughness is one of Nature's best methods of cleansing all parts of the teeth, developing the muscles, and causing normal mucous and salivary secretions. The softer the food the less all these normal functions are in evidence. It is a positive necessity that artificial means should be used to keep the mouth and teeth clean. Morning and night at least the teeth should be scrubbed with a good tooth brush carrying a proper combination of soapy and powdery cleanser. Every surface of each tooth should be brushed, and Luckie says that cheeks and gums should also be carefully brushed, and the mouth then properly flushed with some alkaline cleansing water, and there is none better than the Liquor Antisepticus Alkalinus (N. F.), diluted with one or two parts of warm water.

After each meal the individual should retire to his room or other suitable place, and with thin wooden toothpicks, or with a sharp-pointed quill used gently, and with dental floss, cleanse the cavities between the teeth and then briskly brush the teeth. It would be impossible to estimate the amount of infection that could be prevented should people adopt such a method of caring for their mouths. Also, a dirty mouth may be one of the causes not only of the diseases that have been positively traced to the mouth, such as some instances of pernicious anemia, but of the gradually developing arteriosclerosis and renal disease.

A patient who is actually sick comes under the care of a nurse, and not a small part of her duty is to see that the mouth is kept clean, and frequently cleansed. Patients with chronic disease should be taught, or assistance should be offered them, to use every means to keep the mouth from, by its infected or pathogenic condition, increasing the disturbances that are present.

When purulent conditions or pyorrhea are actually present, active antiseptics should be used as well as alkaline washes. The treatment of chronic inflammation around the teeth, termed Riggs disease, or, better, interstitial gingivitis, is well described by Dr. E. C. Briggs in The Journal, Aug. 1, 1908.

COLD IN THE HEAD

Although this simple affair has already been several times discussed in this department, as it is constantly with us, it is worth while to review what Dr. C. P. Grayson, of Philadelphia (*Therapeutic Gazette*, May, 1909), has to say on this subject. He tells the general practitioners that they have advanced little beyond their professional grandfathers in the prevention or treatment of this inflammation. He wishes to call the attention of the profession to the fact that purulent inflammation of the middle ear, inflammation of the optic nerve, inflammation of the cerebral tissue of the orbit, and even cerebral abscess can all be caused by improper management or neglect of a simple coryza, and this to say nothing of the frequency with which frontal sinusitis and inflammation of the antrum occurs as sequels to the "cold." While the different nasal infections vary in the virulency of the microbal cause, still simple infections can cause serious distant trouble.

Patients who frequently have acute coryza, and especially patients who have more or less chronic coryza, are sure to have some underlying cause. In children this cause is often adenoids. In adults it is often due to hypertrophied and congested nasal mucous membrane, but Grayson says that he has often found such patients, both adults and children, to have an intestinal toxemia.

An acute rhinitis is, therefore, likely to be founded on a tripod of causes, a chronic rhinitis, chronic intestinal toxemia, and exposure to cold (chilling), or to an irritant (dust, germ or other).

Grayson's treatment of acute coryza is as follows:

1. A cathartic, and best one of the ordinary saline cathartics, or a cathartic mineral water. This may be repeated on the following morning, if deemed advisable.

2. The patient should fast for twenty-four hours, and "during this period he should several times, for fifteen or twenty minutes, indulge in the most active exercise of which he is safely capable." Even women and children may be made to take simple active exercise that will bring about the condition desired, viz., "quickened and invigorated heart action, which will cause the skin, bowels and kidneys to become active eliminating organs, and the congestion of the nasal mucous membrane will rapidly subside and its effects be quickly obliterated."

3. If drugs are to be used at all, Grayson advises the salicylates, also a few drops of aromatic spirits of ammonia, or tincture of nux vomica. These drugs will tend to promote excretion. He does not believe in using combinations of opium, belladonna, aconite and acetanilid, all of which more or less inhibit normal secretion and excretion.

If the patient is old or too weak to carry out the exercise suggested, Grayson advises that gentle means of producing diaphoresis be inaugurated, such as a cabinet bath.

Many patients need no local treatment, but if there is much congestion and the patient needs local treatment by the physician, Grayson first uses a preliminary spray of a 2 per cent. solution of cocain, not more than two or three drops into each nostril. This soon shrinks the lower turbinates. Then with a small tuft of cotton on a slender applicator moistened with the 2 per cent. cocain solution he swabs the middle turbinates. The mucous membrane thus being entirely anesthetized and contracted, the nasal chambers are generously flushed with a mild alkaline wash, such as one part of the Liquor Antisepticus Alkalinus of the National Formulary to three parts of warm water. The patient snuffs this solution back into the nasopharynx, and thus the whole nasal cavity is cleansed. The mucous membrane is next soothed by the insufflation of some bland powder, as zinc stearate. Lastly, some bland, non-irritant, thin oil, containing a few drops of a suprarenal solution, may be sprayed into the nostrils, and the sedative effect of the treatment is prolonged.

Medical Missionary Work in China.—The province of Shansi, China, with a population of over 12,000,000, offers an inviting field to the Christian physician. Dr. W. A. Hemingway, a medical missionary of the American Board, has a small hospital at Tai-ku, where he treated 2,177 cases last year, besides a large number of dispensary patients. He is not troubled with rivals, the nearest hospital on the north being 35 miles distant, on the east and south 150 miles, while on the west there is none nearer than Persia. With only two Chinese assistants and two native men nurses, Dr. Hemingway has accomplished wonders since he went out in 1903. Shansi-men are famous all over China for their business ability, especially as bankers. But the entire province, once wealthy, is cursed with the opium habit, and many of its victims come to this hospital for treatment. The price of the drug has doubled lately, thus forcing the poor to abandon its use, and the law is rigidly enforced that the poppy shall not be planted nor opium brought into the province from the outside.

THE RELATION OF THE LIVER TO FAT METABOLISM

It is but a half-dozen years since Hofmeister aroused some attention by adding up the number of different enzymes which each liver cell must contain to accomplish the various chemical functions known to occur in these cells, the total number being something like ten. The worthy German scholar, however, missed some enzymes, for which there was good evidence even at that time, and if he were to rewrite his address now he would show that newer investigations have brought to light several more enzymes that should go on the list. Even with the respectable total of this revised catalogue of hepatic activities before us, we still must feel that as yet we have secured but a most superficial glance at the obvious industries of that busy little workshop, the liver cell, for new investigations into the metabolic activities of the liver continue to unfold new functions hitherto unsuspected, or at least unidentified. As to the enzymes that must be present within each individual microscopic liver cell, their number is augmented with especial rapidity as we learn that to produce any given chemical change several distinct enzymes may be required. As an illustration take the production of uric acid from nuclear material, a property of liver cells which has been known for some time. Closer investigation shows that to bring about this change the following distinct enzymes are required: first, a proteolytic enzyme to free the nucleic acid from the protein; second, an enzyme which frees the purins of the nucleic acid from the rest of the complex; third, two disamidizing enzymes to convert the purins, adenin and guanin, into the oxypurins xanthin and hypoxanthin; fourth, an oxidizing enzyme to convert the oxypurins into uric acid; and in some animals still another oxidizing enzyme may be present which destroys the uric acid.

One of the most recent disclosures of a hitherto unappreciated activity of the liver cell is set forth by Professor Leathes[1] in his substantial lecture before the Harvey Society last winter, and it concerns the rôle of the liver in fat metabolism. That the liver has much to do with the utilization of fat has long been recognized, while physiologists as well as pathologists have struggled with the knotty problems presented by the fatty changes of the liver in health and disease, only recently reaching something like agreement on the fundamental question of the source of the excessive fat in the degenerated organ. This fat, the work of Lebedeff, Rosenfeld and others seems to establish, is not formed from the protoplasm of the liver cell, as the dictum of Virchow maintained, but comes from the fats of the body and the food, and the studies of Leathes and his associates are emphatically in support of this conclusion. But even in health the amount of fat in the liver varies greatly, although practically constant in the other active organs, and this in spite of the fact that in the process of absorption the fats are kept out of the portal blood and turned into the general circulation by the thoracic duct so that the liver does not receive more in proportion than the rest of the body. Analysis of the fats normally present in the liver shows them, however, to be considerably different from the ordinary fats of the adipose tissue and the food in at least one important respect, namely, their chemical activity. We may recall that of the body fats some, such as stearin and palmitin, are relatively inert chemically, while others, notably olein, are much more active chemically because in them are certain carbon atoms whose chemical affinities are not all saturated. The presence of such unsaturated carbon atoms greatly increases the susceptibility of organic compounds to chemical change, and we see evidence of this in the familiar osmic acid reaction for fats, for osmic acid stains black only oleic acid and not the saturated palmitic and stearic acids.

Study of the fatty acids present in the liver under various conditions has led Leathes to suspect that an important function of the liver consists in transforming the relatively inactive, saturated or nearly saturated fatty acids of the fat depots and food into the more active unsaturated fatty acids. To describe this property figuratively, he says: "It looks as if the work of the liver consisted in an operation which may be compared to the drying of gunpowder. The fats we take in our food are remarkably unreactive substances, and it has always been one of the most astonishing chemical achievements of animal cells that they should be able to burn up completely and cleanly, as they do, so stable a structure as saturated fatty acids like palmitic or stearic acids. They are wet gunpowder, and the body stores its gunpowder wet, and safely removed from the inflammatory operations of busily working cells. When the orders for mobilization are issued, this wet powder is conveyed to the drying chambers in the liver, and from there distributed to the fighting line in a proper condition for use. There are times when the stress of this work is manifestly too great. Too active a mobilization of stored fat, or too little activity in dealing with it on the part of the liver, will result in an accumulation of the unfinished product in that organ. A fatty liver is then the result."

This increased accumulation of fat in the liver may take place in starvation, because of the demand of the body for food supplies, which results in the fat being taken to the liver to be so altered that it can be utilized in the production of energy by the active tissues of the body, such as the heart and skeletal muscles. The alteration accomplished by the liver seems to consist in desaturating certain of the carbon atoms in the long chain of the fatty acid, and perhaps also in shifting the location of the unsaturated atoms in the molecule, in order to render these molecules available for chemical changes. According to this interesting hypothesis, therefore, the chief function of the liver in fat metabolism consists in preparing the fats for utilization by other tissues, and not in disintegrating the fats, for such disintegration of the fats in the liver through oxidation would cause the great amount of energy provided by the fats to be liberated in a place where it is not so immediately available as it is in the muscles.

NEW DEVELOPMENTS CONCERNING URIC ACID METABOLISM

In the discussion of gout in his book on metabolism, von Noorden says: "It is not to-day very alluring to write anything regarding the theory of gout, especially in a book which is essentially devoted to the presentation of facts. All the theories advanced up to the present time have fared badly. The positive material is much too insufficient and too ambiguous." While the theory of gout has not been made less hazardous, yet in the few years since v. Noorden wrote this statement the positive material has been considerably increased, and this at the expense of one theory in particular, namely, that gout depends on a loss or decreased power of the body to destroy uric acid. The recent advances have been made particularly through study of the enzymatic actions by which purin metabolism is accomplished, in which work Schittenhelm and Wiechowski have been particularly prominent, although several other investigators have made substantial contributions. The former, with his colleagues, has developed our knowledge of the several steps by which nucleoproteins are converted into free purins, and these, in turn, are changed into uric acid by loss of nitrogen and addition of oxygen. Wiechowski has particularly studied the enzyme concerned in the destruction of uric acid by the tissues, and the fate of free uric acid in the body. This uricolytic enzyme, which has been appropriately called uricase by Battelli and Stern, is an oxidizing enzyme, acting best in experimental digestions when a lively current of air is running through the digestion mixture, and which seems not to be present in the blood plasma and tissue fluids, but only in the cells. It acts rapidly and with striking effect, for active organ extracts are sometimes able to destroy quite considerable quantities of uric acid in a few hours; for example, one gram of powdered tissue, dry weight, can often destroy totally 0.1 gram of uric acid in four hours.[1] Unlike the enzymes of autolytic disintegration of tissues, uricase is not inhibited by the presence of an excess of serum. Another interesting feature is that this enzyme acts reversibly, or at least tissue extracts which destroy uric acid with a current of air running through soon build up the uric acid again when the air is shut off.[2]

Not all tissues contain this enzyme, its distribution, according to the investigations yet made, being as follows:[3] In bovines it is found in the kidney, muscle and liver, but not in the spleen, lungs or intestines; in dogs in the liver, but not in the kidneys, spleen or bone marrow; in the liver of pigs, rabbits and guinea-pigs; in the kidneys and many other organs in the horse, but not at all in the tissues of turtles and geese.

Of particular significance, however, is the observation that, so far as the means at hand disclose, no human tissue whatever possesses any appreciable power to destroy uric acid. There are, to be sure, various early observations which seemed to show at least a moderate uricolytic activity on the part of human tissues, but in view of the more recent work these results must be considered erroneous, perhaps because of faulty technic. The failure of human tissues to destroy uric acid under conditions which permitted complete destruction of uric acid by organ extracts from other mammals was observed by Künzel and Schittenhelm,[4] and later but independently by Wiechowski[5] and Wells and Corper. Using a different method from the above investigators, Battelli and Stern[6] find that, with the solitary exception of man, every mammal which they have investigated—and the number is considerable—possesses uricase in either the liver or kidney. In view of the fact that the human tissues, or at least the human liver, possess the necessary enzymes to manufacture uric acid from nucleoproteins, it is remarkable that man is not able to destroy the product as can all the other mammals. It seems impossible to doubt that this defect is responsible for the tendency of mankind to gout with uric acid deposits, a condition which affects no other mammals, but does occur in birds, which are, like man, devoid of uricolytic enzymes. As corroborative evidence is the fact that swine suffer from a form of gout in which a purin, guanin, is deposited in the tissues rather than uric acid, and swine are peculiar in that their livers do not possess the enzymes which act on guanin (Jones, Mendel).

It might be suggested that these experiments which show the absence of uricolysis in human tissues, having been made *in vitro,* do not prove positively that the living organs within the body are equally devoid of uricolytic activity. This objection may be met, however, by the experiments of Wiechowski, which seem to show that practically all the uric acid which is injected subcutaneously in man reappears unchanged in the urine. The chief product of uricolysis by uricase is allantoin, which has been found more or less abundantly in the urine of every mammal investigated, except man, whose urine contains but traces.[7] This exception in the case of man furnishes good corroborative evidence of the absence or scantiness of active uricolytic enzymes in his body. To be sure, there are to be found statements in the older literature to the effect that pregnant women and new-born infants excrete allantoin in the urine, but Wiechowski finds that the methods then used were entirely unreliable, and Wells and Corper found that human placenta and fetal tissues at all ages were as devoid of uricase as adult human tissues. If man possessed the same uricolytic enzymes as the other mammals it is to be presumed that his urine would contain considerable allantoin, since experiments show that allantoin injected subcutaneously into man all reappears in the urine; the small amount of allantoin that is found in human urine, therefore, is good corroborative evidence that the human body is defective in uricolytic enzymes, a fact of fundamental importance in all considerations of gout and purin metabolism.

SPOROTRICHOSIS

Blastomycetic infection of the skin is now, thanks largely to the investigations of American observers, a well-recognized morbid condition. A considerable amount of literature has recently accumulated dealing with infections, not only of the skin, but of other tissues, by a fungus related to the *Blastomycetes*, the so-called *Sporotrichum*.

Schenck,[1] in 1898, observed a case of multiple, small, very refractory ulcerations of the skin of the right forearm which had formed along the course of the lymphatics leading from an ulcer of the index finger. The ulcers had resulted from the breaking down of small, circumscribed subcutaneous indurations. Cultures were made from the ulcers and indurated nodules, and Schenck's subsequent studies showed that the causative organism was a *Sporotrichum*, a fungus of the order *Hyphomycetes*, which grows readily on all the usual culture media. Schenck was able to reproduce the skin lesions in a dog by subcutaneous injections of the fungus, and, what is most important in the light of recent work, produced a general infection in mice with especial involvement of the lymphatic glands.

Schenck's observations have been verified and augmented by several American and French writers.[2] Sporotrichal lesions of the skin, mucous membranes, lymph glands and muscles have been described. De Beurmann, Gougerot and Vaucher[3] have directed attention recently to the occurrence of sporotrichal infections of the bones, a clinical manifestation which they were led to anticipate from the occurrence of similar lesions in their experimental researches on rats. According to these writers, the periosteum alone may be affected, causing nodular thickenings, or the bone substance itself may be involved, producing a sporotrichal osteomyelitis. Such lesions are said to be easily confused with similar changes of tuberculous or syphilitic origin, and the diagnostic difficulty is increased by the fact that the tibia seems to be the site of predilection for sporotrichal infections. In the cases of bone infection so far recorded, however, characteristic lesions in other structures permitted the detection of the sporotrichum by cultural methods. These observers have also produced joint lesions in rats by subcutaneous injections of the sporotrichum, and they urge a more careful differential study of chronic bone and joint infections with the aid of cultures.

Diagnosis is easy if cultures are made from the lesions, for the organism grows well on all the ordinary culture media in from four to five days at room temperature. It can be demonstrated in the lesions microscopically only with great difficulty. Widal and Weil[4] have shown that the spores of the fungus agglutinate when mixed with the patient's serum at dilutions of from 1-200 to 1-1500, and they describe a complement-deviation phenomenon similar to the Wassermann reaction in syphilis.

Sporotrichal infections show very little tendency to spontaneous healing. Fortunately, potassium iodid in doses up to 90 grains, supplemented by the local application of a solution consisting of water, 500 c.c., potassium iodid, grams 10, iodin, gram 1, is very efficacious, the lesion healing, it is said, in from four to six weeks.

THE VITALITY OF SUPERSTITIONS

Professor Sumner[1] recently conjectured that the civilized world might some day drift back to demonism. The date need not have been left indefinite, so far as at least some portion of civilization is concerned. In the present day there are aberrations quite as peculiar as those which surprise us in reading the history of the middle ages. We may well agree with Lecky that one generation differs from another less in the amount of credulity it evinces than in the direction such credulity takes. Belief in marvelous cures, faith in magic—these things are not dead to-day; at best they but slumber, to be aroused to lusty and malignant activity by the next unscrupulous or fanatical leader. Nor is it any more difficult in this twentieth century, it would seem, to excite emotional epidemics than it was in witchcraft days, or when there were processions of flagellants and dancing manias.

To assure himself of the truth of these gloomy observations, one need but glance through any daily newspaper. Consider, for example, the faith-cure craze but recently revealed in a western state. A bill was introduced before the legislature providing that, in connection with elementary hygiene, public school pupils be taught how to avoid contagion and the commoner ailments. Immediately protests began to pour in from *all* sorts of radical mind-healers, who held that it would be sinful to give children the impression that disease was real; according to newspaper statements, this was the message in hundreds of letters and long petitions. The assembly committee on public health, despite its three physician members, was overawed at the first hearing on the measure, and killed it. Thus has superstition become the match of medical science in shaping the educational policy of public schools.

[1] Sumner, W. G.: Witchcraft, Forum, May, 1909.

All this is depressing enough. Through many painful generations science has been evolving order out of philosophic chaos. This is especially true of medical science, which has accomplished far more than any other factor for the welfare and happiness of mankind; it has come, indeed, to deserve such tribute as was recently paid by an eminent clergyman: "You will find to-day the largest body of disinterested, laborious, self-sacrificing men, looking for no reward and getting no reward except that which comes from faithful service to mankind, in the profession of medicine." A century and more ago Jenner demonstrated how a dreadful pestilence need never again afflict our fellows; yet to this day would the mind-healer have us revert to its medieval horror. Von Behring has shown how deaths from diphtheria can be avoided for little children; to this very day would the faith-curist stand over children suffering from this disease, trusting to prayer only, and withholding the sure relief, while they expire from suffocation. Pasteur and Koch have shown how tuberculosis can be eliminated from human experience; the Eddyites would press the conviction (and, amazing to state, do convince some) that this disease is non-existent. Better than this it were, indeed, to revert to voodooism; for the latter has, at any rate, the sense to believe in tuberculosis and to seek a material remedy.

SANATORIUMS AND PROPERTY VALUES

The National Association for the Study and Prevention of Tuberculosis *has collected evidence showing that* well-conducted sanatoriums, dispensaries and camps for sufferers from tuberculosis are not detrimental to any community; that, on the contrary, their presence tends *rather to enhance than to depreciate its property values.* Recently, the subject has been studied, continuing an investigation conducted four years ago by William H. Baldwin,[1] of Washington, D. C., and for a summary of this study we are indebted to the *Survey*. Thirty-seven institutions were considered, and these were located in twenty-two states, as diverse in situation as Maine and California, as Oregon and Georgia. According to sanatorium authorities, real estate agents, as well as various disinterested people, more than 67 per cent. of these sanatoriums have favorably influenced the property surrounding them, and have otherwise benefited their respective communities. Twenty-three (62.2 per cent.) of these institutions helped definitely to increase assessed valuations. In only one instance was there a decrease in value, and this is considered to have been due to ignorance of the facts. In twenty-two cases among the thirty-seven the sanatorium facilitated the sale of land; in only four cases was any detrimental effect on sales shown. In more than half the cases, residents were attracted by the sanatorium, and in only three localities were they repelled. In the vicinity of a sanatorium in Portland, Oregon, land has more than doubled in value in three years, being in demand close to the institution; at Aiken, S. C., property in the neighborhood of the local sanatorium has increased fourfold since its erection; at Asheville, N. C., vacant lots near one of the sanatoriums sell at four times their price in 1900, and others farther from the institution but nearer the city are less valuable; at Hebron, Me., surrounding property has increased 20 per cent. as a direct result of the presence of a tuberculosis sanatorium. Similar effect on land values is reported from Luzerne, Pa., Liberty and Saranac Lake, N. Y., Pittsford, Vt., Mount Vernon, Mo., and Silver City, N. M. In St. Louis, Philadelphia, New York, Brooklyn, Boston, Pittsburg and other large cities, property surrounding tuberculosis institutions has increased in price; not a single instance was reported in which the presence of a camp, dispensary or sanatorium in a large city has had a detrimental effect on contiguous property. It is noted that the courts of Massachusetts, North Carolina and Virginia have decided that a tuberculosis sanatorium is not a menace to the health of a community, or to the property in its vicinity.

Much of the lay opposition to the sanatorium in the past has been due to misconception of the nature of infection in tuberculosis. Nor is it yet universally understood that in this disease the virus is not air-borne; *that practically all infection from consumptives to their* fellows is through the medium of the sputum, and that when this is properly disposed of there is no danger. The fight against tuberculosis sanatoriums has frequently been bitter, and sometimes virulent; it has nearly always been occasionless and based on ignorance. Poor Bodington, who in 1840 established the first institution on our modern principles of phthisiotherapy, had to succumb to it; on which, with much relevance, he turned his institution into an asylum for the insane. Next came Brehmer, who, fortunately for humanity, weathered superbly the cyclonic storms which beset him. Since 1854, when he began his work at Goerbersdorf, that village, fortunate in its defeats at his hands, has trebled its population; it has become vastly prosperous; it is now ready to accommodate any number of sanatoriums, and there are to-day within its hospitable limits at least five such institutions.

This is fast becoming the universal experience. There is no place so safe from tuberculosis infection as a well-ordered sanatorium; in nineteen years no nurse or other attendant or any servant contracted tuberculosis in the institution the destinies of which are directed by Trudeau; would any one dare say as much of any city home in which there has been a consumptive? The sanatorium has always had a commercial value, the nature of which was soon grasped by the astute agriculturist; it needs every day enormous quantities of butter, eggs, milk, cream, meats—and why should not these staples, as well as the labor required, be furnished by its neighbors? In cities, also, merchants have found these institutions a stimulus to trade. The sanatorium, moreover, raises local health standards; it becomes a school in which the vicinity learns the principles of hygiene and prophylaxis. Besides, the very fact of a given locality being selected for a sanatorium site is a surety and a gratuitous advertisement that it is a salubrious region, and this tends to make the place a profitable "health resort," and helps real estate agents to get "cottages" and other similar buildings erected.

---

[1] Property Benefited by Tuberculosis Sanatoriums, Survey, June 19, 1909, xxii, 422.

THE PREVENTION OF MALARIA

Malarial disease is so familiar to us in its milder forms that few, even of experienced practitioners, have an adequate conception of what its actual cost in human life and human health is in the aggregate in our country. Figures which may be assumed to be reliable, as quoted by Dr. Seale Harris in his article in this issue, give us a mortality, as he says, greater than that of any or all the epidemics of yellow fever in the last half century. Taking into account that mortality is a very poor index of the actual damage done by this disease, since Dr. Harris says that probably not one in five hundred of those affected dies, these figures are sufficiently formidable. It is the morbidity caused by malaria, however, that is the factor mainly to be considered, and the importance of this can hardly be overestimated. Without going into the usual calculations of the value of human life and health from a financial standpoint, there is sufficient evidence of the evil to be found all over the world in deserted regions which were formerly centers of active and thriving populations. In spite of this, malaria is a preventable disease and this waste of human life and health can, to a very large extent at least, if not entirely, be avoided. Even in the tropics, where the conditions are most unfavorable, as in the Malay States and Panama, it has been shown that it can be permanently stamped out. These facts show that the problem is not so difficult as it appears, and we have had sufficient object lessons of the ease with which it may be accomplished in some parts of the Middle West where chills and fever, once very prevalent, have almost entirely disappeared, from the ordinary methods of opening up the country with cultivation and drainage. Dr. Harris' recommendations that malaria should be made a reportable disease and the patients isolated, may be difficult to carry out in some communities, but they are not impracticable and with the proper education of the people the difficulty would probably soon disappear. This can be accomplished, as he says, by means of lectures and tracts, etc., and, still better, by the individual efforts of those who are already enlightened on the subject. The benefit of a national association for the study and prevention of malaria is well illustrated by the experience of Italy, in which country the mortality and morbidity have been very largely reduced. Malaria prevention may sometimes raise interstate questions and the necessary measures cannot be always efficiently carried out by local legislation. Still, any community can protect itself against indigenous infection, unless very exceptional and extraordinary conditions exist. It is not ordinarily essential that the aid of the national government be invoked, but, in order to carry out the larger drainage enterprises that may be advisable, its help will be exceeding useful if not absolutely necessary.

Medical News

FLORIDA

Personal.—Dr. Henry C. Dozier, Ocala, has been appointed local surgeon for the Atlantic Coast Line, vice Dr. William H. Powers, deceased.——Dr. Gaston Day has been appointed city physician of Jacksonville.

Bacteriologic Laboratory.—Tampa has donated a site for a branch laboratory of the State Board of Health, and the board has decided to locate in that city. The state will erect a building to cost about $30,000. Dr. Howard S. Holloway, who has been in charge of the Jacksonville office, will take charge of the temporary laboratory to be used until the completion of the new building.

Tuberculosis Sanatorium Donated to State.—Dr. John E. Ennis, who has conducted for several years a private tuberculosis farm sanatorium near Kissimmee, has offered to donate the property to the state on condition that it is to be thoroughly equipped and so conducted as to prove of benefit to the greatest possible number of tuberculosis patients. The proposition has been accepted by the State Board of Health, and the board has acquired by donation sufficient land to make a total of 100 acres, located in Hendon Park, with a frontage along Hendon Lake. About $87,000 is at present available for the establishment and maintenance of the farm.

ILLINOIS

Hospital Opened.—It is announced that Graham Hospital, Canton, was opened about October 5.

Personal.—Dr. Ora L. Pelton, Jr., Elgin, has started for Europe.——Dr. Otto R. Scott, Chrisman, who has been critically ill, is reported to be improving.——Dr. and Mrs. Bernard Fantus, Chicago, have returned from Europe.

Antispitting Crusade.—The Board of Health of Rock Island has inaugurated a crusade against expectoration, and has posted placards calling attention to the fact that persons spitting on sidewalks will be subject to a fine of $5.

Free Health Advice to Working Men.—The Occupational Disease Commission announces that a publicity campaign will be inaugurated with the cooperation of state officials and medical experts. The scope of this work will include hints for workers and employers on every occupation of injurious nature, extending to household occupations.

Investigate Pellagra.—Following an investigation by the president of the State Board of Charities, and others, into the pellagra conditions at the Peoria State Hospital, South Bartonville, Secretary W. C. Graves is to submit a report to the governor recommending that a committee of physicians and biologists be authorized and appointed to make a complete investigation into the disease.

State Conference of Charities.—The fourteenth annual meeting of the Illinois State Conference of Charities and Correction will be held in Peoria October 9-12, under the presidency of William C. Graves, secretary of the State Board of Charities, Springfield. Among the more important features of the convention are addresses on "Occupations for the Blind," by Charles F. F. Campbell, Cambridge, Mass., superintendent of the Industrial department of the Massachusetts Commission for the Blind, and vice-president of the National Society for Workers Among the Blind; "Clinical Organization of State Hospitals," by Dr. William L. Russell, state inspector of state hospital service for the New York Commission in Lunacy; "Adult Probation," by Warren F. Spalding, secretary of the Massachusetts Prison Association; "Care of Needy Families in their Homes," by Marcus C. Fogg, district superintendent of the Pittsburg Associated Charities; "Medical Supervision of Public Schools," by Dr. James Stewart, medical supervisor of the St. Louis public schools. The president will respond for the conference and will speak briefly on "The Relation of the New State Charities' Administration Law to the State Conference of Charities and Correction, and to the City and County Governments."

INDIANA

To Aid the Work Against Tuberculosis.—Responding to the appeals of the Evansville Antituberculosis Society, the Vanderburg county council, at its annual meeting, September 7, appropriated $1,000 for the work against tuberculosis.

Personal.—Dr. Mary E. Jackson, Hammond, while making a professional call, September 22, fell through a rotten porch and suffered a fracture of the left patella and severe contusions.——Dr. John I. Metts, Ossian, is reported to be critically ill with cerebral hemorrhage.——Dr. Charles R. Dancer, Fort Wayne, has been appointed city medical inspector of schools.

MASSACHUSETTS

Test Pupils for Typhoid.—In order to prevent further spread of typhoid fever among school children of the Brighton district, the chairman of the Board of Health has had cultures taken from each of the 4,500 school children of that district.

Inauguration of Harvard's President.—The program for the inauguration exercises of the new president of Harvard University, Abbott Lawrence Lowell, October 5-7, contains the following items of interest to medical men: At 2:30 p. m., October 6, the Harvard Alumni Association will meet in Memorial Hall; and on Thursday afternoon the Faculty of Medicine and the Harvard Alumni Association will be hosts at an afternoon tea at the medical school, Longwood avenue.

Personal.—Dr. James V. W. Boyd, Springfield, has been named to succeed Dr. Herbert C. Emerson, resigned, as health inspector and physician of the Fourteenth district.——Dr. Clarence I. Sparks, Easthampton, has been named medical examiner for the Hampshire district, vice Dr. William G. Kimball, Huntington, resigned.——Dr. Henry A. Christian, dean of Harvard Medical School, delivered an address at the dedication of the new medical building of Leland Stanford, Jr., University, and was entertained at luncheon by the medical faculty of Epworth Medical University and Oakland County Medical Society, September 17.——Dr. J. W. Crawford has agreed to take charge of the tuberculosis camp established by the Young Men's Christian Association of North Adams.

MINNESOTA

Zone of Quiet.—Alderman Bow, a member of the Minneapolis council committee on health and hospitals, will introduce an ordinance for the establishment of a zone of quiet to be maintained in the vicinity of all hospitals in the city.

Personal.—Dr. S. Scott Blacklock, Hibbing, was recently operated on for appendicitis and is making a good recovery.——Dr. Hannibal H. Kimball, Minneapolis, has returned from Europe.——Dr. William C. McCarty, Rochester, had his right hip dislocated in an automobile accident at Ogden, Utah, September 21.

Experiment with School Medical Inspection.—The Board of Education of Duluth has decided to establish temporary medical inspection in four schools of the city as an experiment, and if this prove satisfactory, the inspection will be adopted by the board for all schools, and the cooperation of the parochial schools will be asked. Dr. Samuel H. Boyer is the medical member of the committee on schools and teachers which formulated this plan.

State Medical Society Meeting.—The annual meeting of the Minnesota State Medical Association will be held in Winona October 12-14, under the presidency of Dr. Cornelius Williams, St. Paul. The oration in medicine, on "Administration Problems in Relation to the Public Health," will be given by Dr. Walter Wyman, Surgeon-General U. S. P. H. and M.-H. Service, Washington, D. C., and symposia on the following subjects, "Epidemic Anterior Poliomyelitis," "Cooperation of State Forces in Minnesota Medicine," "Ophthalmia Neonatorum," and "Typhoid Fever, a Medical and Economic Problem as Illustrated by the Classical Mankato Epidemic of 1908."

MISSOURI

Quarantine Time Extended.—The St. Louis Board of Health has increased the quarantine period for scarlatina from four weeks to six weeks.

County Society Purchases Stereopticons.—The St. Joseph-Buchanan County Medical Society has purchased two large stereopticons for use in the course of postgraduate study, suggested by the American Medical Association, which the society has commenced.

Hospital Staff Appointed.—The winter staff for the new Kansas City General Hospital has been appointed as follows: Attending staff surgeons—Drs. Jabez N. Jackson, Albert H. Cordier, Jefferson D. Griffith, John F. Binnie, Herman E. Pearse, B. Clark Hyde, Howard Hill, John M. Frankenburger and Ernest F. Robinson; assistant surgeons—Drs. James P. Henderson, A. Comings Griffith and Ottokar Hofman, Jr.; physicians—Drs. John L. Robinson, Samuel C. James, Robert T. Sloan, Charles C. Conover, Otho L. McKillip, Franklin E. Murphy, Hugh D. Hamilton, and J. M. Lowe. Consulting staff: Obstetrics—Drs. Caleb A. Ritter and George C. Mosher; pediatrics—Drs. Clay S. Merriman, Harry L. Heller and Jesse E. Hunt; gynecology—Drs. George B. Norberg and C. Lester Hall; otology and laryngology—Dr. James E. Logan and David L. Shumate; ophthalmology—Drs. Flavel B. Tiffany and Andrew W. McAlester, J [illegible] Halsey M. Lyle and William Frick; [illegible] George W. Davis, Jacob Block and Ernest G. Mark; neurology—Drs. John Punton, Henry O. Hanawalt and Rush E. Castelaw; skiagraphy.—Drs. Edward H. Skinner and Oliver H. McCandless; and pathology—Drs. Frank J. Hall and Otto L. Castle.

NEW MEXICO

New Mexico Red Cross.—The New Mexico branch of the National Red Cross elected the following officers at the annual meeting, September 17: President, Dr. George W. Harrison, Albuquerque; vice-president, Dr. James W. Laws, Lincoln, and secretary-treasurer, Dr. John W. Colbert, Albuquerque.

Antituberculosis Society Organized.—At the meeting of the New Mexico Medical Society, a New Mexico branch of the National Society for the Study and Prevention of Tuberculosis was organized with the following officers: President, Dr. Francis T. B. Fest, East Las Vegas; vice-president, Dr. John W. Colbert, Albuquerque; and secretary-treasurer, Dr. Leroy S. Peters, Silver City.

NEW YORK

New York City

Personal.—Dr. Smith Ely Jelliffe has just returned to New York to his practice after a year spent in study in Germany and France.

Sea Breeze Home Closed.—The Sea Breeze Fresh Air Home maintained by the New York Association for Improving the Condition of the Poor was closed on September 30. During the summer 22,687 women and children have been taken to this home for one-day stays and 4,171 for stays averaging between eight and ten days.

Good Service by Field Hospitals.—Occurrences along the line of march of the parades during the Hudson-Fulton celebration showed that the field hospitals were well organized and entirely efficient for the service they had undertaken. All were busy at one time or another. The majority of cases were those of persons who had fainted, though there were several instances of epileptic fits and a number of heat prostrations. The number of injured was not great.

Another Milk Depot.—Nathan Straus, whose work of supplying pasteurized milk for babies has entered on its eighteenth year, has added another milk station to those already maintained by him. This makes the eighth permanent depot which he maintains all the year around. In the year just ended the Straus stations have supplied 3,410,105 bottles of pasteurized milk and during the past summer at the stations in the parks and on the piers 1,523,251 glasses of pasteurized milk were served.

Buffalo

Medical College Opens.—The University of Buffalo began its sixty-fourth regular session Monday evening, September 27. Dr. Peter W. Van Peyma, professor of obstetrics, delivered the opening address.

Personal.—Dr. Herbert H. Glosser is taking a three months' post-graduate course at Vienna.——Dr. Herbert D. Pease has resigned as director of the state hygienic laboratory, New York State Department of Health.

NORTH CAROLINA

Gunshot Wounds.—Dr. P. L. Hagler, Birmingham, was shot and seriously wounded by William McIntyre recently.——Dr. J. Lewis Hanes, Winston-Salem, Pine Hill, while hunting, shot himself in the thumb, which was afterward amputated.

Warning Against Lithia Water.—The *Bulletin of the North Carolina State Board of Health* for August officially announces that "the water sold by the Buffalo Lithia Springs Water Company of Buffalo Lithia Springs, Va., and by Smith's Lithia Water Company of Oxford, N. C., has been found by three successive analyses made by the State Laboratory of Hygiene, to be dangerous to public health."

OHIO

Take Patients on Probation.—The State Tuberculosis Hospital, Mount Vernon, will be ready to receive patients October 15. All patients will be received on four weeks' probation.

Antituberculosis.—At the meeting of the Antituberculosis and Health League of Allen County, held at Lima, September 17, Drs. William E. Hover, Albert S. Rudy, William H. Parent and James B. Poling, Lima; George S. Weger and James R. Tillotson, Delphos, were elected trustees, Dr. James B. Poling, Lima, was elected secretary, and George E. Johnson, Auglaize, and Richard E. Jones, Gomer, were elected township vice-presidents. The trustees, by unanimous vote, indorsed Dr. William E. Hover, Lima, for president of the league.

Personal.—Dr. Estell H. Rorick, formerly superintendent of the Athens State Hospital and the State Institution for the Feeble-Minded, is reported to be seriously ill with lung disease at The Dalles, Ore.——Dr. William L. Jackson, Newark, is convalescent after a severe attack of ptomain poisoning.——Dr. Ernest S. Brooks has been appointed physician in charge of the Cleveland Tuberculosis Sanatorium, Warrensville, vice Dr. Joseph C. Placak, resigned.——Drs. John D. O'Brien and Henry C. Eyman, Massillon, have sailed for Europe.——Dr. Judson A. Hulse has been made school inspector of Akron, vice Dr. Dan M. McDonald, resigned.——Dr. Mason O. Wert, Poplar, sails for Europe October 12.

Cincinnati

Flag Day.—Superintendent Withrow of the Antituberculosis League announces that Flag Day will be held October 16, when it is expected to dispose of 100,000 large and small American flags, the proceeds to be used in carrying on the work of the league against tuberculosis in Cincinnati, and the establishment of a large tuberculosis pavilion at the branch hospital.

Personal.—It is announced that President Dabney of the Ohio-Miami Medical College will assume the duties of dean for the time being.——Dr. Frazier X. Monroe has received a government appointment and has been detailed for duty in the Canal Zone.——Dr. Oliver P. Holt was operated on recently for appendicitis at Rochester, Minn.——Dr. John L. Waffenschmidt is reported to be critically ill.

PENNSYLVANIA

State Society Election.—At the fifty-ninth annual meeting of the Medical Society of the State of Pennsylvania, held in Philadelphia, September 27-30, the following officers were elected: President, Dr. Theodore B. Appel, Lancaster; vice-presidents, Drs. Charles A. E. Codman, Philadelphia, Henry H. Riegel, Catasauqua, Joseph W. Albright, Muncy, and Charles W. Bachman, Reading; secretary, Dr. Cyrus L. Stevens, Athens; treasurer, Dr. George W. Wagoner, Johnstown; trustees, Drs. William A. Nason, Roaring Spring, John B. Donaldson, Cannonsburg, and David H. Strickland, Erie; and delegates to the American Medical Association, Drs. George W. Guthrie, Wilkes-Barre, Alexander R. Craig, Philadelphia, John B. Lowman, Johnstown, Horace G. McCormick, Williamsport, and Americus R. Allen, Carlisle. The next annual meeting will be held in Pittsburg.

Philadelphia

Personal.—Dr. J. William White has been elected a member of the Fairmount Park Commission.——Dr. Harry Lowenburg has been made instructor in pediatrics in Jefferson Medical College.

Reception to Dr. Cook.—At the conclusion of his lecture in Philadelphia, on September 29, Dr. Frederick A. Cook, the Arctic explorer, was entertained at a banquet by the Medical Society of Pennsylvania, then in convention.

Criticize City's Institutions.—The grand jury for the September term visited the city's penal and charitable institutions and found them generally in fair condition. They reported light and ventilation lacking to a considerable degree in some of the older buildings. They criticized the over-crowded condition at the Philadelphia General Hospital.

Health Report.—The total number of deaths reported for the week ended October 2, reached 390. This is a decrease of 50 from the number reported in the previous week and a decrease of 62 from the number reported in the corresponding week of last year. There were 134 cases of contagious disease reported with 18 deaths as compared with 128 cases and 9 deaths reported in the preceding seven days.

Abnormal Pupils to Receive Proper Care.—It is reported that there are 442 mentally deficient and physically abnormal children in the city's public schools and the authorities have planned to have these children committed to institutions where they can receive proper attention and treatment. This movement is the first step toward the abolition of special schools and the establishment of classes for backward and deficient pupils of the elementary grades. A committee of five psychologists has been appointed to look after this work by the superintendent of public schools, Dr. Simon S. Brumbaugh. Those who show the slightest traces of normality, or who can, by scientific methods, be put on a plane with the average child, will be treated at the psychologic clinic of the University of Pennsylvania.

SOUTH CAROLINA

Physician Enjoined.—In the case of J. W. Crawford, charged with the practice of medicine at Donalds, Abbeville county, without license, and under a temporary restraining order obtained from Judge J. W. Klugh, August 31, the court on September 4 held the medical practice act constitutional, and made the injunction permanent.

Personal.—Dr. Francis A. Coward has been placed in charge of the laboratory recently opened at Columbia by the State board of health.——Dr. J. R. Wilkinson, Charleston, medical missionary to China, of the Southern Presbyterian Church, sailed from Vancouver September 6.——Dr. J. William Folk, in charge of the Georgetown quarantine station, South Island, has resigned.——Dr. Louis C. Barbot, Charleston, received severe injuries in a runaway accident September 3.

TENNESSEE

To Care for Tuberculous Poor.—Dr. Henry P. Colle, president of the Knoxville Association for the Prevention and Relief of Tuberculosis, reports that the association will soon build an institution for the isolation and treatment of the tuberculous poor of that city.

Colleges Open.—At the opening of the medical department of the University of Chattanooga, September 22, the matriculation address was delivered by Major Charles R. Evans, dean of the law department.——The medical department of Lincoln Memorial University, Knoxville, formerly known as Tennessee Medical College, opened for the year, October 1.

TEXAS

New Cottages.—Managers of the state insane hospital have awarded the contract for two cottages for tuberculosis patients, to cost $35,000.

New Sanitary Code Adopted.—At the meeting of the state board of health, in Austin, September 14, the sanitary code was adopted and transmitted to the governor for his approval. The board decided to spend $15,000 on the state quarantine station.

Personal.—At the regular quarterly meeting of the Seventh Councilor District Medical Society, held in Austin, September 23, Dr. Washington A. Harper was elected president, vice Dr. Matthew A. Taylor, deceased.——Dr. Frederick W. Kirkham, formerly of Cuero, has moved to Brownsville, and has been appointed health officer of Cameron county.

Ruling on New Medical Statute.—The attorney-general's department has ruled that a physician licensed to practice in 1901, but who has no recent verification license, as prescribed by the act of 1907, cannot legally practice medicine by virtue of the license originally issued, but that it will be necessary for him to go before the present medical board, be examined, and obtain a license from the board.

VERMONT

New Sanitarium.—Dr. Grace W. Sherwood has purchased the Herbert Brainerd House, St. Albans, and will open a private sanitarium to accommodate 10 patients.

State Medical Society Meeting.—The ninety-sixth annual meeting of the Vermont State Medical Society will be held at White River Junction, October 14 and 15.

Medical Society Elections.—The Rutland Medical Reporting Club was organized September 9, with the following officers: President, Dr. Mark R. Crain; vice-president, Dr. William W. Townsend, and secretary-treasurer, Dr. Ray E. Smith.——At the annual meeting of Washington County Medical Association, held in Montpelier, September 21, Dr. Orlando G. Stickney, Barre, was elected president; Dr. Lester W. Burbank, Cabot, vice-president; Dr. Edwin A. Colton, Montpelier, secretary, and Dr. Louis A. Russlow, Randolph, treasurer.

Medical Staff Election.—At the annual meeting of the medical staff of St. Albans Hospital, September 22, Dr. John Gibson was elected president and Dr. George C. Berkley secretary. Drs. Edwin A. Hyatt and William B. Arnold, St. Albans, and Fred S. Hutchinson, Enosburg Falls, were appointed to arrange terms of service for the medical staff, to make weekly visits to the hospital, personally to inspect the sanitary condition of the building and grounds and examine the foods and medicine. Dr. Waldo J. Upton was elected a member of the staff of lecturers of the training school for nurses.

VIRGINIA

Colleges Open.—The annual session of the Medical College of Virginia, Richmond, opened September 14, Dr. Christopher Tompkins, the dean, delivering the address of welcome.——The annual session of the University College of Medicine, Richmond, opened September 14.

Personal.—Dr. Stanley H. Graves, Norfolk, has been appointed a member of the State Board of Health, vice Dr. Charles R. Grandy, Norfolk, resigned.——Dr. W. H. O. McGehee, dean of the dental department of the University College of Medicine, Richmond, has resigned and will remove to Cincinnati, where he has been elected professor of operative and clinical dentistry, and superintendent of clinics in the Ohio College of Dental Surgery.——Dr. William R. C. Booker, Bristol, was seriously injured, September 1, by being thrown from his horse.

Medical Societies Meet.—At the annual meeting of the Tidewater Medical Society, held in Urbanna, the following officers were elected: President, Dr. William P. Jones, Urbanna; vice-presidents, Drs. J. W. Dorsey Haynes, Cobb's Creek; John N. DeShazo, Center Cross; Alfred C. Palmer, Richmond; and Claybrook Fauntleroy, Dragonville; and secretary-treasurer, Dr. George W. Brown, Saluda.——At the annual meeting of Elizabeth City County Medical Society, held in Hampton, Dr. J. Wilton Hope was elected president; Dr. William H. Howard, vice-president, and Dr. Harry D. Howe, secretary-treasurer.

Coroners' Association Meets.—At the meeting for organization of the Virginia Coroners' Association, September 21 and 22, the following officers were elected: President, Dr. Lucien Lofton, Emporia; vice-presidents, Drs. John W. Brodnax, Manchester, and H. Gilbert Leigh, Petersburg; secretary, Dr. McCandlish M. Moran, Pinners Point; treasurer, Dr. Joel Crawford, Yale, and executive committee, Drs. H. Gilbert Leigh, Petersburg; Edmund H. Lewis, Culpeper, and William H. Taylor, Richmond. The association recommended that a state law be enacted requiring the appointment of coroners for the 66 counties of the state in which there is at present no such officer for the protection of the people and investigation of suspicious cases, and that a law be enacted requiring all embalmers to use the same embalming fluid, which should be free from chemical poisons.

GENERAL NEWS AND COMMENT

Hospital Association Election.—At the annual meeting of the American Hospital Association, held in Washington, D. C., September 23 and 24, the following officers were elected: President, Dr. Herbert B. Howard, Boston; vice-presidents, Drs. John N. E. Brown, Toronto, Ont., and Dr. Wayne Smith, St. Louis, and Miss Mary L. Keith, Rochester, N. Y.; secretary, Dr. Warren L. Babcock, Detroit, and treasurer, Mr. Asa Bacon, Chicago. St. Louis was selected as the place for the 1910 meeting.

Society Meeting.—At the annual meeting of the American Electro-Therapeutic Association, held in New York City, September 28-30, the following officers were elected: President, Dr. Thomas D. Crothers, Hartford, Conn.; vice-presidents, Drs. Thomas H. Cannon, Baltimore, Md., and Frank E. Peckham, Providence, R. I.; secretary, Dr. J. Willard Travell, New York City; treasurer, Dr. Richard J. Nunn, Savannah, Ga., and board of trustees, Drs. Charles R. Dickson, Toronto, Ont.; Morris W. Brinkmann, New York City; Herbert F. Pitcher, Haverhill, Mass.; Francis B. Bishop, Washington, D. C.; Edward C. Titus, New York City; Fred H. Morse, Boston, Mass. The next annual meeting will be held in Saratoga in September, 1910.

Conference on Pellagra.—The National Conference on Pellagra will be held in Columbia, S. C., November 3 and 4, under the auspices of the State Board of Health of South Carolina. Physicians and sanitarians are cordially invited to unite with the local profession in the study of the disease. Although the malady is of comparative recent recognition in this country, it already has been reported from seventeen states and is assuming the proportions of a national public health problem. The conference will include not only addresses, papers and discussions, but a number of clinical cases will be presented, thus affording the profession an opportunity for study of the disease. More detailed information may be obtained on application to Dr. Charles F. Williams, Charleston, secretary of the board, and state health officer.

Vital Statistics of Cuba.—Dr. Matias Duque, Havana, Secretary of Sanitation and Charities of Cuba, in his report for August, gives the following report of vital statistics of Cuba for May: The number of deaths registered was 2,398, equivalent to an annual rate of 12.95 per 1,000. An increase was observed in the following diseases: Infantile diarrhea, circulatory diseases, meningitis, cerebral congestion and hemorrhage, tetanus, influenza and cirrhosis of the liver. A decrease was noted in tuberculosis, acute bronchitis, bronchopneumonia, and pneumonia, cancer, nephritis and typhoid fever. Of the decedents 740 were under 1 year of age, 275 from 1 to 5 years of age, and 1,383 from 5 to 8 years of age; 1,617 were white and 781 colored. During the month 6,732 births were reported.

Health of the Philippines.—In the report of the Bureau of Health for the Philippine Islands for the quarter ended June 30, Dr. Victor G. Heiser, director of health, notes the completion of the first collection of lepers from every province of the island, excepting Moro Province. During the quarter, 685 lepers were collected and transferred to Culion. The conditions at Culion have undergone a change for the better, due to improvement in environment and the experiment that has been made on some patients by the Chaulmoogra oil treatment. The investigation into the typical town with special reference to the presence of intestinal parasites, shows that about 10 per cent. of the deaths were from uncinariasis and about 95 per cent. from some intestinal parasite. The death rate for Manila for the quarter was at the annual rate of 29.55 per 1,000, the lowest rate recorded, with one exception, since American occupation. A number of buildings of the Philippine General Hospital, for which appropriation was made last year, are now actually under roof. The legislature has decided that the institution shall be a division of the bureau of health, and it will be managed and known as the Philippine General Hospital Division of that bureau.

Mississippi Valley Medical Association.—Extensive preparations are being made by the St. Louis Medical Society of Missouri and the physicians of St. Louis for the entertainment of the members of the Mississippi Valley Medical Association which meets in that city October 12-14. The municipal boat has been offered by the health officer and mayor for a visit to the city water works and a trip along the water front of the city. Several hundred seats have been secured at vaudeville theaters for one evening. An automobile ride has been arranged for the ladies accompanying the members, and many other functions are in process of arrangement. The subject of the symposium is to be "Exophthalmic Goiter," which will be participated in by Drs. S. P. Beebe, New York City; George W. Crile, Cleveland, Julius H. Jacobson, Toledo; Allen B. Kanavel, Lewis J. Pollock, Albert J. Ochsner and Arthur R. Elliott, Chicago, and Herman Tuholske, St. Louis. Among other important and interesting topics for discussion are "Pellagra," on which papers will be read by Passed Assistant Surgeon Claude H. Lavinder, U. S. P. H. and M.-H. Service, and Dr. Joseph J. Watson, Columbia, S. C., with exhibition of patients and "Uncinariasis," on which a paper will be presented by Dr. Charles Wardell Stiles, Washington, D. C., chief of the hygienic laboratory, U. S. P. H. and M.-H. Service.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Sept. 25, 1909.

Precautions Against the Importation of Cholera from Holland

Elaborate precautions have been taken against the importation of cholera from the continent. All vessels coming from Rotterdam are medically inspected at Gravesend and no passengers are allowed to land until their addresses of destination have been given. The vessels which convey large numbers of passengers are fitted with wireless telegraphy apparatus and messages will be sent to the health officer of the port of London should any illness of the nature of cholera arise during the voyage. While in port the vessels are inspected daily and all their refuse is burnt. No drinking water will be taken on board at Hamburg and no water will be carried in the ballast tanks. While the vessels are in port at Rotterdam their decks are not to be washed with river water. If the outbreak extends to other parts of Holland from Rotterdam all the Dutch ports may be declared infected; arrangements have already been made for dealing with vessels ariving from Flushing. Vessels arriving from St. Petersburg are subjected to special supervision and many passengers arriving with insufficient addresses have been detained on board for inquiries. A Russian captain who allowed some detained passengers to land has been fined. Quarantine has been abolished in this country and a system of medical inspection and supervision of persons arriving from infected ports has been substituted.

Socialization of the Medical Profession

In Great Britain, as in all civilized communities, great development is taking place in the control of the state over public health and the medical profession is becoming much concerned as to the effect of the rapid changes on its interests. Recently the government appointed a commission to inquire into the working of the poor-laws, which has resulted in a most important report foreshadowing revolutionary changes in the poor-law system. As a large part of poor-law relief consists in medical treatment and a majority of the physicians in rural districts hold poor-law appointments and clubs, the profession is deeply concerned. The clubs are a form of contract practice; the members principally belong to the working class and make a small annual payment—about $1—which insures them medical advice and medicine during illness. Most physicians are glad to get these appointments, as they bring in a fixed income, unlike the income derived from private practice, which depends on a varying amount of illness and varying ability and willingness to pay. When the physician also holds a poor-law appointment, for which he always receives a fixed stipend, he is only too glad that the agricultural laborers should join his club, for otherwise they would probably go on the parish during illness and he would have to attend them without any additional payment. Now the report of the poor-law commission foreshadows great changes—a more extensive system of free medical relief by the state, a vast system of contract practice, an unprecedented restriction of private practice, constituting indeed a veritable socialization of the medical profession. Curiously, though, the medical profession is in politics very conservative, it has for many years been unconsciously a force driving in the socialistic direction. Public health legislation has been created and extended largely as a consequence of its advice and demands. The system of free and compulsory public education, adopted in its complete form only in recent years, has involved another socialistic consequence for which the profession is largely responsible. The folly of compelling the diseased or underfed child of the artisan to attend school for instruction which his physical condition renders him unfit to receive soon became apparent. The very conservative London county council, which came into power entirely on the anti-socialistic cry, has been driven to provide free meals for necessitous children. Now the problem is how to deal with the various ailments, such as ear disease, adenoids, defective vision, etc., which interfere with education. Two propositions have been discussed—to establish school clinics under paid medical officers for the treatment of the children, or by making a grant to arrange with the hospitals for treatment of the children. As the cost of the former would be enormous, the council has decided on the latter course and has already made arrangements with some of the hospitals. But the British Medical Association, which may be taken to represent the views of the medical profession as a whole, has condemned this proposal after a discussion at the recent annual meeting. The association characterized the proposal as an abuse of the voluntary charity of hospitals which were never intended for the purpose of assisting the state to do its duty, and also as very inadequate, for the work to be done is much greater than the hospitals could undertake in addition to their present duties. It might be said in reply, however, that most of the children belong to the very class which it is the duty of hospitals to assist. If the school clinics be established this will be another great step in the socialization of the profession, for the children who attend the government schools comprise the classes ranging from the very poor to those of the skilled artisan and the small shopkeeper—classes on which most of the profession depend. Further, it is only a short step from the free treatment of these children to the free treatment of their parents.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Sept. 22, 1909.

Mr. Harriman's Death and the Vienna Medical School

The news of the death of the American railroad magnate, who for some time was under the care of one of our best-esteemed professors in Vienna, has caused some unpleasant discussions in the papers. The charges of wrong diagnosis hurled at the Vienna physicians by some transatlantic journals have prompted the physician who was treating Mr. Harriman here to answer publicly. He asserted that the diagnosis (inoperable cancer of the stomach) was indubitable when he saw the millionaire the first time. It was important to keep the knowledge of the true state of things from the unhappy man; but the American physicians accompanying Mr. Harriman were fully instructed here, if they needed any instruction at all. Mr. Harriman was sent, on the advice of the Vienna physician, to a diagnostic sanatorium near Munich. This again was complained of by the Austrian papers as being unfair to the Austrian sanatoriums, which could solve the question "cancer or no cancer" equally well. The reason was given that the physician, coming from Germany, still adhered to German places. Anyhow, the entire discussion was disgusting and proved once more the truth of the old principle: "The less one speaks of his patients to laymen, the better."

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 16, 1909.

Overcrowding of the Medical Profession in Germany

The unfavorable economic situation of the medical profession in Germany is emphasized by new statistics in which the disproportionately greater growth of the medical profession as compared with the population since the year 1885 is exhibited. While the population of the German Empire from 1885 to 1907 increased somewhat more than 32 per cent., the number of licensed German physicians increased more than 102 per cent. (in 1885, 15,764; in 1907, 31,864). In 1885 there was one physician for 2,963 inhabitants; in 1907 one to only 1,973—a proportionate increase three times as great as that of the population. To this must be added the fact that through the social legislation the number of patients available for private practice has been extraordinarily limited. In 1885, 4,294,173 persons were insured against illness; in 1907, on the other hand, the number was 11,721,796.

Personal

Prof. H. Kossel, director of the hygienic institute at Giessen, has received a call to Heidelberg in the same capacity, and will move thither in April, 1910. As is well known, his elder brother, the distinguished physiologist, Prof. A. Kossel, is employed at the same university.

September 2, Prof. V. Hensen, the well-known physiologist at Kiel, celebrated the semicentennial of his doctorate.

As a result of a fall, Professor Jaffé, chief surgeon of the city hospital at Posen, died September 2.

September 5, Dr. Agnes Hacker, one of the oldest and most noted women physicians, died here in Berlin. Among other positions, she held the presidency of the association for establishing a woman's hospital in Berlin.

Schools for the Deaf

At the Budapest congress, Professor Hartmann, the head of a department of the Berlin Rudolf Virchow Hospital, gave an address on schools for the deaf. Hartmann learned by investigation that there is a not inconsiderable number of children in the public schools who remained for years in the lowest classes on account of a pronounced difficulty of hearing, are regarded as feeble-minded, and are retarded in their intellectual development, and he succeeded seven years ago in having established by the support of the city authorities of Berlin a special course of instruction for children with marked difficulty of hearing. At present there are in Berlin 17 classes for the partially deaf. Experienced instructors of the dumb, each of whom has charge of only ten children, act as teachers. The principals of the schools send the children who, on account of deafness, are not making progress, for investigation, accompanied by the teacher. In the presence of the director of the school for the deaf, the children are individually examined. In many cases it is ascertained that the deafness depends on a disease of the ear that may be improved or cured. Among the children received 28 per cent. were still affected with suppuration of the middle ear and 52 per cent. with growths in the nasopharynx. By determining the children's power of hearing it has been shown that many, in spite of a high grade of dulness of hearing, were still capable of profiting by the ordinary instruction. The degree of the power of hearing, therefore, is not alone sufficient to decide as to admission into the schools for the deaf. A very important factor is the ability of the child to learn. A great injustice would be done to those hard of hearing if they were classed with the feeble-minded. Furthermore, the deaf must be completely separated from the dumb. The observations made at the examination for admission and at later examinations, showing that a considerable number of the affections of the ear are amenable to treatment, indicate that there is an urgent demand for the examination of the deaf by a specialist on their admission into the school.

The Campaign Against Tuberculosis

The city of Charlottenburg has acquired a large tract of woodland in the neighborhood of Berlin as a site for a hospital for the treatment of patients with advanced tuberculosis. In this institution pulmonary invalids are to be received, whose removal from their homes is necessary in the interest of the public health. If possible, the patients are to remain in the hospital as long as they live. In addition, mild cases of lung diseases are to be received, especially such as are fit for the sanatoriums but cannot be admitted for lack of room, and also such as have been discharged from the sanatoriums but still need supervision. Two hundred beds are provided with the possibility of expansion to 300 beds. After the erection of this new tuberculosis hospital only such cases of consumption are to be received in the Charlottenburg city hospital as must be taken in on account of sudden severe illness or those that are temporarily or permanently unfit to be moved. By this plan the city of Charlottenburg is carrying out the suggestion of Koch and other authors to render harmless by permanent confinement in a hospital such advanced cases as cannot be isolated in their homes so as not to endanger their healthy neighbors. The success of the campaign against tuberculosis in Germany in late years is shown by the following recently published statistics on deaths from tuberculosis in 350 cities of the German empire with 15,000 and more inhabitants:

Deaths from pulmonary tuberculosis:
In 1899, 22.6 per 10,000 inhabitants living.
In 1904, 19.3 per 10,000 inhabitants living.
Deaths from tuberculosis in general:
In 1905, 22.3 per 10,000 living.
In 1908, 19.2 per 10,000 living.

The question of institutions for the care of pulmonary invalids was taken up at the annual meeting of the German Public Health Association *(Deutsches Verein für öffentliche Gesundheitspflege)* a few weeks ago. No new points were made in this discussion, as, in general, the whole tuberculosis question has temporarily fallen into a rut.

The Significance of the Trachoma Corpuscles

The etiologic signficance of the trachoma corpuscles, like that of the *Spirochæta pallida*, was considerably shaken at the Budapest congress. As is well known, Greeff and von Prowazek-Halberstädter have found peculiar corpuscles in the conjunctivas of trachoma patients, to which they attribute an etiologic as well as diagnostic importance. Prof. B. Heymann reported investigations which he had made in the Breslau Hygienic Laboratory, under the direction of Professor Pfeiffer, in which he found these corpuscles in a considerable number of other conjunctival diseases. Of 9 cases 5 were fresh trachoma lesions and 4 were cases of gonorrheal ophthalmia neonatorum. Heymann, in his article recently published in the *Deutsche medizinische Wochenschrift*, comes to the conclusion that it is not practicable to assert that the corpuscles of Prowazek are specific for trachoma, so long as we have no means of differentiation between them and the corpuscles found in gonorrhea, and that the Prowazek corpuscles are of diagnostic value only when all suspicion of gonorrhea is excluded. But even if these structures are specific for trachoma, no conclusion as to their etiologic relation to that disease should be drawn.

Epidemics of Poliomyelitis

Epidemics of poliomyelitis like those in Sweden in 1905 and last year in Austria have broken out in several places in Germany within a few weeks. Such an epidemic was first reported from Hamburg and Schleswig-Holstein. Lately cases have occurred in the Rhine country and Westphalia. Now an epidemic is prevalent also in the province of Brandenburg and in Hesse. It affects young children almost exclusively, in whom paraplegias, hemiplegias and monoplegias are observed. In one case a superior polioencephalitis also occurred. By an order of the ministry of education (*Kultusministerium*) Professor Krause, director of the policlinic at Bonn, was sent to Westphalia to investigate the cause and extent of the disease.

Sale of Medical Practice

By a decision of our highest court, the German Imperial Court (*Deutsches Reichsgericht*), a contract for the sale of a physician's practice is opposed to good morals and therefore invalid. A short time ago the Swiss Federal Court (*Schweizer Bundesgericht*) reached an opposite decision. The Swiss decision is to the effect that the disposal of a physician's practice cannot be regarded as illegal, but a physician who has paid a definite price for a practice cannot later dispute the contract on the ground that it is an unethical transaction. To be sure, the physician has ideal duties to perform toward his clientele, but, on the other hand, the calling of the physician has its material side, and these material interests, like those of other trades, may become the subject of a contract. Just as no one has a right to complain of the physician because he charges a fee for his services, so no objection ought to be made if he accepts a price from his successor for his introduction and delivery of his practice.

BUDAPEST LETTER

(From Our Special Correspondent)

Budapest, Sept. 10, 1909.

[An account of the scientific proceedings of the Congress will be found in the Department of Society Proceedings.]

The Political Incubus

Looking back over a number of international scientific congresses I can hardly remember a congress at which, as to-day at Budapest, the atmosphere was so heavily charged with political considerations. There was a good deal of politics at Washington last year at the Tuberculosis Congress, and, strange to say, the fight was much the same. Of course I am fully aware that 90, I hope 99 out of every 100 medical men who read these lines will exclaim that science knows no frontier, that science is not political, that science in the service of humanity seeks only for truth. In 1889, the Paris Universal Exhibition and some of the scientific international congresses were partly boycotted because these were held in celebration of the centenary of the great French revolution. Nevertheless, in the great hall of the Paris Sorbonne, before some three thousand representatives of the science and art of healing, Pasteur and Lister met face to face on the platform and then, with one common accord, embraced. That one thrilling moment was worth all the politics that have ever been spoken or written; the governments had sought to boycott the French nation and its government, but the greatest benefactors of the human race embraced.

Are Government Delegates Impartial?

It is unfortunately an actual fact that it is impossible to keep politics completely out of these congresses. There are, however, two sorts of politics; one which has a legitimate right of entry and the other about which not so much as a whisper should be heard. Of the former, I spoke at some length in my last letter. It is the politics of social reform. Nothing will prevent medical men, hygienists and chemists from declaring that we must have pure air, pure water and unadulterated food. Yet how many political fights have taken place to secure such legislation as we possess, which purports to provide these fundamental necessities of existence! Indirectly all scientific congresses must deal with politics of this description. Indeed, what would be the use of proclaiming the basic principles on which health is to be preserved if nothing practical is to be done to ensure their application?

War and the Americans at the Madrid Congress

There are also acute political situations that arise at the great international congresses of medicine and the allied sciences that cannot possibly be avoided, at least so far as the members of the congress themselves are concerned. One of the most exciting which I have witnessed was at Madrid where the International Congress of Hygiene and Demography met just at the very moment when the Cuban war broke out between the United States and Spain. In the very heart of Madrid, close to the *Puerto del Sol*, an American insurance company possessed a very fine building which it had thought fit to decorate with American eagles carved in stone. One of these spread its wings in a particularly aggressive manner, so some excited Spanish patriots went up and hacked at the sculpture till it fell down with a crash into the street below. But it so happened that, in its fall, the American eagle struck the wooden staff of a Spanish flag and down came the flag as well as the bird. For so superstitious a people as the Spaniards this was an evil omen. What, however, was my concern to observe immediately after this incident, a group of American army and navy surgeons strolling through this very neighborhood in full uniform. To the honor of the Spanish populace be it said, not a stone was thrown, not a threat or an insult was proffered, a dignified silence was maintained, thus showing once more that the poorest classes in Spain can set the world an example in matters of dignity and courtesy. This incident, I trust, will be remembered; and, when this self-same congress meets next year in the United States the Spanish delegates will be made to feel that their American hosts can appreciate how the American delegates were treated in Madrid under very difficult, trying and painful circumstances. Though war was declared before the congress was over not a single American met with any rudeness at the hands of the Spanish.

War Dangers and the Budapest Congress

At the Budapest congress, if we have not had war we have had such menacing rumors of war that, at one moment it was very doubtful indeed whether the congress would be held. Undoubtedly, if the present political situation could have been foretold, three years ago at Lisbon, no one with any sense of prudence would have accepted the Budapest invitation. But really we who voted for Budapest at Lisbon in 1906 never dreamed that by 1909 Austria-Hungary would have torn up the treaty of Berlin and taken forcible possession of Bosnia and Herzegovina. For a long time it seemed as if war were inevitable, and though peace has been maintained, what to many would have seemed the most interesting after event of the congress has been spoiled. Just as many medical men went to the Madrid congress because they hoped to visit Andalusia afterward and contemplated the beauties of Seville, the Alcazar and Granada, so others were tempted to Budapest by the hope that, after the Congress, there would be an excursion through the Balkan Peninsula to Constantinople, coming home via Athens. This is exactly what happened in 1894, and well I remember the magnificent receptions we had and the wonders we saw. But nothing of the sort is possible to-day. The result of this trying political situation is that there have been no official excursions. As individuals, of course, members of the Congress could go wherever they liked, paying the ordinary price and guided by the ordinary excursion agencies. But the governments of the countries concerned made no offer, proposed no sort of reception or entertainment. Thus the political situation weighed heavily on the congress and this through no fault or blunder of the congress itself.

Racial Conflicts Within the Congress

The Roumanians, as is well known, for they sent out a circular to all the medical press, boycotted the congress, because Mme. Vlad, the wife of a Roumanian deputy in the Hungarian parliament, was sent to prison for urging Roumanian children to persevere in the study of their mother tongue. It would take much time to discuss this question of languages which is somewhat wide of the mark. There is a great deal to be said on both sides. By order of the emperor, Mme. Vlad was released, and versions differ as to the extent of her offense, if offense there was. But what concerned the congress even more than this incident, though it deprived us of the presence of the medical practitioners from the neighboring state of Roumania, was the circular addressed to all the German physicians attending. It was posted from Vienna and issued by the society for the maintenance of the German nationality in Hungary. The circular commenced by stating that it understood the German delegates to the congress had been invited to a banquet at which the principal host is to be the minister of public worship and public education, Count Apponyi. The circular then abused, in violent language, the minister for practically excluding the German language from the elementary schools and accused him of making liberal speeches abroad while carrying out the most illiberal policy at home. The circular concluded: "We anticipate that we shall appeal with success to the national sense of honor of all Germans when we ask you, one and all, to refuse as one man, this man's invitation. Nevertheless, we are fully convinced that the scientific side of the congress will suffer no injury through such a manly action on your part." Now the awkward thing is that, instead of throwing aside this extravagant manifesto, a large number of German medical men who had accepted the invitation to dinner, swore off at the last moment. Only a few sent lame excuses, several did not even do that much. On the other hand, I would hasten to add that the Germans, after twenty-four hours' reflection, sobered down considerably and many were present the next day at the Park Club where Count Apponyi gave a brilliant reception and supper. This incident shows how largely political questions intrude on scientific congresses. Then we have the Poles. A terrible blow has been struck at them, and this was the doing of the congress itself. In voting for the creation of a permanent commission for the organization of these congresses, the word "nation" was struck out and "state" substituted. Thus the little state of Luxenburg has a member on the commission, but the Polish delegate, who claimed to speak on behalf of 24,000,000 Poles, was ruled out; because, if there is a Polish nationality there is no Polish state. This vote will not fail to encourage the Hungarians who are endeavoring to prevent the separate existence of the Germans, Slovaks, Roumanians, Ruthenians, Croatians and Servians, though together they equal about half the population of Hungary. In this war of races, religions, languages and, at the back of it all, of economic interests, what has the medical profession and what have international medical congresses to say? "Nothing at all," is, of course, the most obvious and certainly the easiest answer. But is it the true answer?

Where a Congress Cannot Be Neutral

The language question does not concern us, but all the week we have been shown institutions connected with education and the medical relief of the poor. Surely the language question is at the foundation of the education question; and if medical men are not to be interested in the general education of the peoples and nations they visit, I am sorry for medical men. Everything that interferes with the mental and physical evolution of man, interests the medical profession. Wherever children are overcrowded and starved in school, whether these schools be religious or secular, there the medical profession is concerned; and how appalling, how deplorable is the state of elementary education in Hungary! Where economic conditions are such that there is not even a sufficient subsistence wage to be earned, there the medical profession is concerned; and in America, something is known of the starvation which has driven so many Hungarians over the Atlantic. The agrarian party, the great landed aristocracy which holds Hungary in its grip, presented to the congress a glowing picture of the progress that has undoubtedly been accomplished. But the true student will look below the surface. A model operating theater at Budapest with an extravagant display of modern and expensive surgical instruments does not mean that throughout the country similar perfection prevails. Nor must a congress allow itself to be utilized as a means of fostering the belief among other nations that the country where its meetings are held is the home of all the virtues and all progress. This, I trust, will not be the aim of the organizers of the next congress of hygiene when it meets in Washington, or the next congress of medicine when it meets in London.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Sept. 16, 1909.

The White Cross Society and Food Adulterations

Two years ago a society called the Universal White Cross Society of Geneva (*Société Universelle de la Croix-Blanche de Genève*) was founded to unify efforts against tuberculosis, cancer, syphilis, epidemic, infectious and parasitic diseases, alcoholism and morphinism, food poisonings, diseases of poverty, etc., made by national and international institutions throughout the entire world, thus affording a permanent bond of union, while leaving each one in absolute internal and local independence. For the purpose of securing international agreements for the repression of adulterations in drinks, foodstuffs and agricultural products, the society organized last year the first International White Cross Congress at Geneva and this year it is organizing a congress which will be held at Paris, October 17-24.

The Geneva congress took up the problem of adulterations from a new point of view. It endeavored to define, not adulterations, but the normal type of each form of foodstuff. In all countries striving to suppress food adulterations legislation has been passed and chemical analysis called on to establish adulteration, regardless of the fact that often an analysis of an adulterated food has no practical value unless compared with an analysis of the clearly defined normal type. The Geneva congress having defined these types, the Paris congress will consider the operations necessary to the manufacture of commercially pure foodstuffs.

The congress will meet under the patronage of the heads of several of the departments of government and will be divided into three sections. The first, presided over by M. Müntz, member of the Academy of Sciences, will be concerned with the technology of food. The second, presided over by Dr. Landouzy, dean of the Paris medical school, will examine from the point of view of hygiene the questions discussed by the first section. The third, presided over by M. Guignard, director of the Superior School of Pharmacy and member of the Academy of Sciences, will be concerned with adulterations of drugs, chemical products and mineral waters.

Night Medical Service at Paris

Apropos of the fact that recently the father of a child who fell sick during the night was unable to find a physician soon enough, some political journals have criticized our night medical service severely. In a general way, however, it may be said that this service is very satisfactory and its workings are sufficiently ingenious to merit description.

This service begins at 10 p. m. and ends, during winter, at 7 a. m., during summer at 6 a. m. Every physician who desires to be placed on this service has himself inscribed on the list of "night physicians." Any one wishing to call a night physician has to address himself to the nearest police station. A police agent then accompanies this person to the residence of the physician, follows the latter to the patient's home, and, the visit being concluded, takes him home again. The service is not free. For each visit the physician receives $2 (10 francs), paid out of the municipal funds. According to the means of the patient, as discovered after inquiry, the administration requires from the patient reimbursement of the physician's fees, or assumes the cost itself.

Obstetric cases are taken care of by midwives, whose fees are $4 (20 francs) for each delivery.

The night medical service has been organized in this way since 1876. Ten years after its organization a night pharmaceutic service was also created. The pharmacists, enrolled at their request, receive 30 cents (1 franc 50 centimes) as a fixed return for each order they fill in addition to reimbursement for the cost of the drugs.

The number of physicians participating in the night medical service at present is about 596; of midwives, about 477; and of pharmacists, about 468. Last year there were 14,000 night medical visits, for which the doctors received $28,000 (140,000 francs). Out of this sum the administration received from the private individuals who required physician's services, only $6,000 (30,000 francs).

New Treatment for Obesity

All the methods of treatment of obesity rest on the double rule of diminishing food and increasing elimination; but chiefly on the former, since most obese persons have depleted nervous systems and are incapable of accomplishing the necessary effort to increase their organic outlay by muscular work. Dr. Bergonié, professor of biologic physics and medical electricity at the Bordeaux medical school, has met the difficulty, obtaining artificially intense muscular activity by causing an alternating electrical current of 8 to 12 volts and of an intensity of 50 milliamperes to pass through the body of the patient with a frequency of 40 to 100 per second. The patient reclines over a large electrode, the other electrode covering the greater portion of the anterior surface of the body. Under these conditions, the passing of the current is absolutely painless. Under the influence of the current all the important muscular masses (thighs, calves, buttocks, back, shoulders) are animated with muscular contractions sufficiently energetic to elevate the body, even when weighted down at the level of the thighs by a weight of 88 pounds (40 kilos) or more.

According to Dr. Bergonié's recent communication to the Academy of Sciences (*Académie des sciences*), and to the French Association for the Advancement of Sciences (*Association française pour l'avancement des sciences*), this treatment will cause a very rapid diminution of the weight of fat, if the patient is careful to maintain his diet at a ratio inferior to that which corresponds to his muscular outlay; it will, moreover, increase strength and resistance to fatigue.

Pharmacology

WATERBURY'S METABOLIZED COD-LIVER OIL COMPOUND

Report of the Council on Pharmacy and Chemistry and Laboratory Contribution on Which It Is Based

The following report has been adopted by the Council and its publication directed.

W. A. PUCKNER, Secretary.

To the Council:—Your committee on pharmacology has read with interest the contribution from the Association's laboratory on Waterbury's Metabolized Cod-Liver Oil Compound. The report shows that misleading and false statements are made in regard to the composition of the product and also that exaggerated and unwarranted claims are made for its therapeutic value. In view of the attempt of the Waterbury Chemical Co. to create a false impression in regard to the therapeutic value of the composition of its product, it is recommended that the following report be adopted and published:

The Council believes that there is a preponderance of evidence to indicate that whatever therapeutic value cod-liver oil has, that value depends chiefly, if not entirely, on its fat (oil). In the opinion of the Council, the word cod-liver oil should not be used in connection with any preparation unless it consists to a large extent (25 per cent. or more) of cod-liver oil. Since Waterbury's Metabolized Cod-Liver Oil Compound contains no appreciable quantity of cod-liver oil, the name is incorrect and misleading, and as a cod-liver oil preparation it is believed to be wholly valueless. The Council has previously voted that Waterbury's Cod-Liver Oil Compound be refused recognition because of conflict with Rules 1 and 6.

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

Waterbury's Metabolized Cod-Liver Oil Compound

W. A. PUCKNER AND L. E. WARREN

A full page advertisement of Waterbury's Metabolized Cod-Liver Oil Compound appeared in the *Iowa Medical Journal*, March 15, 1909, in the form of a letter purporting to give the results of an analysis of the product made for the firm by a Chicago chemist. In this letter-advertisement the chemist states at the outset that the results of his examination "are somewhat at variance with the statements made in THE JOURNAL." These statements he quotes as follows:

> 1. It is a clear liquid and no globules of oil are seen under the microscope It is therefore not an emulsion.
>
> 2 It is of acid reaction when mixed with water and remains clear when strongly acidified. Hence it does not contain a soap, and is not a saponification of fat.
>
> 3 It mixes with water without precipitation, hence, it can not contain more than traces of a fatty acid.

The chemist admits in his letter to the firm that his analyses verify statements 1 and 3, but regarding statement 2 he says: "I find that your preparation is acid in reaction, but when strongly acidified gives a distinct turbidity within 10 minutes and a voluminous precipitate within 1 hour. This precipitate is shown to consist of fatty acids of cod-liver oil, which are thrown down by the splitting of the soaps, on acidifying either with sulphuric or hydrochloric acid." From these results he states that to him it seems that the "preparation does not deserve the statement that it contains no soap, as there is no question whatever of the presence of cod-liver oil."

While in the letter published in this advertisement the chemist claims to have demonstrated the presence in the product of "saponified cod-liver oil" he *omits to mention the quantities* of the soap present. In the article that originally appeared in THE JOURNAL (Oct. 13, 1906), in addition to the three paragraphs quoted by the chemist, the following statements were made:

"By these simple tests a physician is easily able to demonstrate that the preparation does not contain cod-liver oil. It is therefore valueless for the purpose of nutrition for which we give the oil. More careful analysis confirms the results of these tests and shows that it contains no fat or fatty acids (except the merest traces) . . ."

At the time these statements were published in THE JOURNAL, the *St. Paul Medical Journal*, October, 1906, contained an advertisement for Waterbury's Metabolized Cod-Liver Oil Compound, which contained this statement:

> "The only tasteless preparation on the market which contains Cod-Liver Oil in its entirety. The metabolized product is obtained by the action of digestive ferments on pure Cod-Liver Oil."

In the *Ohio Medical Journal* of Feb. 15, 1907, there appeared in the form of an advertisement what purported to be an analysis of Waterbury's Metabolized Cod-Liver Oil Compound by Prof. C. N. Kinney of Drake University. While Professor Kinney made a quantitative analysis of the preparation the quantities were omitted from the analysis as published. A footnote added by the Waterbury Chemical Company called attention to this fact and closed as follows:

"Any physician who is not satisfied with the analysis we will be only too glad to furnish the complete analysis by our representatives."

If this weirdly constructed sentence meant anything, it meant that the complete analysis would be furnished on request. Such requests to the company, however, from various sources failed to elicit the information required nor was the "complete analysis" forthcoming. The inference to be drawn is fairly plain.

In a circular accompanying the product as sold at present, this statement occurs:

WATERBURY'S
METABOLIZED COD LIVER OIL COMPOUND
With Creosote and Guaiacol or Plain

DOES CONTAIN COD LIVER OIL
DOES ALLAY FERMENTATION
DOES AID DIGESTION
DOES ASSIST ASSIMILATION
BUT DOES NOT DISTURB THE STOMACH

As previous examinations disclosed only the merest traces of cod-liver oil in the product while claims were made that it "represents cod-liver oil in its entirety," and in view of the fact, too, that present advertisements emphatically declare that cod-liver oil is present in the preparation as now sold, it was thought best to examine some of the preparation with especial reference to the quantities of fatty acids from cod-liver oil.

The results of the examination, the details of which are given below,[1] are briefly as follows: The total quantity of acids isolated amounted to about 0.3 per cent., and of this amount about two-thirds was *salicylic acid.* Thus it appears from the examination of the specimens bought on the open market that the preparation contains at most but 0.1 per cent. of the fatty acids from cod-liver oil, a totally insignificant quantity.

Notwithstanding the protestations by the manufacturers, in the form of published analyses and circulars, it is seen that the statements published in The Journal, Oct. 13, 1906, p. 1207, are essentially substantiated; it is further evident that the product does not deserve to be designated as a cod-liver oil preparation. To obtain a medicinal dose of cod-liver oil the patient would be compelled to swallow the contents of a bottle of this mixture, and as, the product contains 11 per cent. alcohol the patient who did so would probably experience a degree of exhilaration not referable to cod-liver oil.

---

[1] A trade package of Waterbury's Metabolized Cod-Liver Oil Compound was purchased in the open market and examined in the Association laboratory. The product was a pale brownish-yellow, very slightly turbid liquid having an acid reaction and a malt-like odor. The odor was in no way suggestive of cod-liver oil or of cod-liver oil preparations. When strongly acidified with hydrochloric acid no precipitation or increase in turbidity was observable at once as would be the case were soaps present in appreciable amounts. On standing over night the acidified solution gave a flocculent precipitate. On shaking the acidified solution with ether-chloroform mixture and evaporating the solvent, a brownish, partially crystalline residue was obtained, the greater proportion of which appeared by qualitative tests to consist of *salicylic acid.*

Ether-Chloroform-Soluble Matter: A portion was strongly acidified with hydrochloric acid and extracted with an ether-chloroform mixture. The solvent was washed with water, evaporated, the residue dried at 98 C. and weighed; 500 c.c. of the product gave 1.5222 gm. or 0.3044 gm. per 100 c.c. Attempts to separate the salicylic acid quantitatively from the fatty acids by crystallizing the former from hot water were not entirely successful.

Free Fatty Acids—Salicylic Acid: The ether-chloroform-soluble residue was treated with hot water and filtered. The residue on the filter was dissolved in warm alcohol, the solvent evaporated to dryness, the residue treated with hot water to remove salicylic acid, and filtered. The undissolved residue on the filter was dissolved in warm alcohol, filtered and the filtrate evaporated to dryness, the residue dried and weighed as free fatty acid; 500 c.c. gave 0.0362 gm. in the first separation. The first crop of salicylic acid crystals, which separated from the hot water filtrate on cooling, was filtered out, the filtrate evaporated to small bulk and allowed to crystallize a second time. The first and second crops of salicylic acid were united, dried at 60 C., and weighed; 500 c.c. gave a total of 0.8421 gm. salicylic acid, or 0.1684 gm. per 100 c.c. A second yield of fatty acids was obtained from the filtrate from the salicylic acid separation by the process employed for the first, 0.0201 gm. being obtained. Total fatty acids isolated amounted to 0.0566 gm., or 0.011 gm. per 100 c.c. This residue gave the Pettenkoffer test for bile products thus indicating the probable presence in the preparation of traces of products derived from cod-liver oil.

The filtrate, from which the fatty acids and salicylic acid had been separated so far as possible, was evaporated to dryness, the residue dried at 98 C. and weighed. A residue of 0.2595 gm. was obtained. This residue did not give Pettenkoffer's reaction for bile salts. It consisted of salicylic acid, free fatty acids and undetermined substances. Since 0.8421 gm. salicylic acid was separated from the residue or 55.3 per cent. of the total, it follows that not more than 0.6804 gm. or 44.7 per cent. of the initial residue can possibly be free fatty acids, or 0.13 per cent. as calculated on the entire sample. This value is evidently much too high as it includes everything in the initial residue not obtained as crystallized salicylic acid. It was noticed during the examination that whenever a fatty acid residue was dissolved in alcohol a noticeable residue remained which was also insoluble in water. Adding the several residues obtained, 0.8421 gm., 0.0566 gm. and 0.2595 gm., the sum of 1.1582 gm., is obtained. Subtracting the sum from 1.5222 gm., the initial residue, a loss of 0.3640 gm., is noted. As a check on the above the total acids were determined in a sample of 100 c.c. An ether-chloroform soluble residue of 0.330 gm. was obtained.

DR. CURRY CANCER CURE COMPANY

The Exploiters of a Cruel Fraud Put Out of Business by the Postal Authorities

In one of the chapters in *Collier's* "Great American Fraud" series by Mr. Adams, the "cancer cure" quack was shown up.[1] Among the numerous humbugs in this line of business, Dr. G. M. Curry, of Lebanon, Ohio, was apostrophized under the caption, "An Ananias of Quackdom," as follows:

"I don't want to overrate Dr. Curry in his own department of human activity, but he seems to me, on the whole, one of the most eminent all-around liars I have encountered anywhere in Quackdom. According to his own statements, Dr. Curry has discovered not only the germ of cancer, but also a sure cure for it."

This and much more did Mr. Adams have to say about Dr. Curry. Attention was called to the fact that in his enterprise Curry had the support of Lebanon's "best citizens"—the county treasurer, the sheriff, the recorder, the auditor, a judge, two attorneys, and two bankers, to say nothing of several other prominent inhabitants.

Said the élite: "Dr. Curry is no quack. His remedy is no fake. Both are entitled to the fullest confidence of cancer sufferers and Lebanon is proud of his success." Later in the series Mr. Adams told how valiantly the Lebanon newspapers came to the defense of Curry and his cruel fake. Nevertheless, even as long ago as July, 1906, Mr. Adams ventured this opinion: "Dr. Curry *is* a quack. His remedy *is* a fake. And the highly respectable citizens who bolster it are, giving them the benefit of the doubt, the dupes of an arrant swindler." Now, three years later, comes the United State Government in the person of Assistant Attorney-General Goodwin, and says some equally unkind things about the business which Dr. Curry built up. From the report which Mr. Goodwin transmitted to the Postmaster General, we abstract the following:

THE CURRY CANCER CURE COMPANY

This company was engaged in treating, through the mails, patients afflicted with cancer. E. W. Ramsey was its secretary and manager and the advertisements informed prospective patients that their letters might be sent to him if they preferred, in order to insure secrecy. What the company claims for its cure is indicated by the following quotations:

"Cancer cured in 10 days—a discovery that has startled the medical world. I have discovered what the medical world has been looking for, for years. A sure cure for cancer, so sure that it can be absolutely guaranteed. This I do and I can prove. I have cured hundreds of the most horrified cases in from 10 to 20 days after celebrated physicians and surgeons had given up all hope of saving them."

When a victim answered an advertisement, pamphlets and testimonials were sent to him, together with a question blank, on which he was to indicate the symptoms of his disease. In a circular letter the statements were made:

"It certainly gives us pleasure to be able to say to you that we have a positive cure for this, one of the most dreadful diseases that afflicts the human race. We are sending you free the necessary information that will show you how to cure yourself at home in from 10 to 20 days without the aid of a physician or surgeon and at little expense.

---

[1] See pages 77 and 116, "Great American Fraud" pamphlet.

"The disease of cancer baffled the skill and science of the medical profession for centuries and was always considered an incurable malady. Now the discovery of the Curry method of curing and removing cancer, root and branch, is considered by many medical men to be one of the most important advancements in medical science of this age. By means of this treatment no trace of the disease is left to propagate any further growths or again endanger the life of the sufferer. We have cured hundreds and hundreds of cases of the most malignant and aggravated form where hope had been all but permanently abandoned by the sufferer and the case about to be pronounced incurable.

"If you faithfully follow our directions this treatment should absolutely cure you, remove all traces of the cancer poison from the blood, and prevent you from either suffering further yourself or transmitting the horrible malady to your descendants and causing untold suffering in future generations."

Attention was called to the fact that it was not necessary to come to the "sanitarium" in order to be cured. The company has "perfected a home treatment, so that you can cure yourself of your cancer just as well right in your own home." As a sample of some of the claims made, we may quote:

LYING CLAIMS

"The most desperate cases successfully treated by the Curry cure."

"The percentage of deaths from cancers which have been treated with the Curry cure is absolutely down to nothing."

"The Curry Cancer Cure has stood the test. The anti-toxin for diphtheria was an- immediate success because it could stand the test."

"If you have a cancer or a suspicious growth on any part of your body act now before it is too late. If your cancer is far advanced you may die from it in a month or in a week. You can not tell what moment will be your last. After you have used the treatment for a day or two and you find that your pains are gradually leaving you, that the cancer is diminishing in size and that the soreness and bleeding is fast disappearing then you will know that death has been cheated and instead of the grave there awaits you more years of health, sunshine and happiness. Then, too, you will realize why the Curry Cure stands foremost among the world's great discoveries."

FOLLOW-UP LETTERS

The victim was fully informed that by answering the questions on the blanks sent him the company would be able to study his case "from the standpoint of successful specialists." If no reply was received to this letter, the company again wrote the prospective patient, urging him to send in the question blank properly filled out, immediately, and impressing him on the danger of delay. If this brought no answer another letter was sent to him telling him that the company had taken a deep-seated interest in his case and felt certain that it could cure him. If a reply was still not forthcoming, another letter was sent, asking the patient to explain the delay and telling him that he probably would have been cured months ago if he had but cast aside prejudice and answered the questions submitted to him.

In those cases in which the question blank was filled out, the company sent the victim a letter in which it stated that it could cure him permanently by its treatment in from ten to twenty days at a cost of $25. If the money was not forthcoming, a series of follow-up letters was sent to the patient, in which it was represented that within twenty days' time from the commencement of treatment, the cancer would be cured absolutely, never to return; that "every fiber, filament and tendril" would be rooted out and that the place where the cancer was would be healed over with healthy skin and all signs and danger of cancer would have disappeared forever.

At its hearing the company submitted samples of the "remedies" by which these marvelous results were purported to be brought about. They were analyzed in the Department of Agriculture and the findings of the department, which were transmitted to the postmaster general, were in part as follows:

THE GOVERNMENT'S LABORATORY REPORT

"The value of the above remedies in the treatment of cancer is summarized as follows:

"Nos. 7, 8, 9, 10 and 18 are simply antiseptic substances useful only in rendering surfaces to which they are applied cleanly and free from outside infection.

"Nos. 19, 21, 24 and 20, 22 and 23 are all also antiseptic and the latter three, in addition, contain opium, which to some extent allays pain of the part to which applied in these cases, the rectal or vaginal passages.

"Nos. 25 and 26 are simply tonic medicines.

"No. 17 is a preparation of opium which deadens the system to the sensibility of pain.

"No. 16, a cocain preparation which relieves pain temporarily by its local paralyzant action on the tissues to which it is applied.

"No. 15, an astringent which may be used in stopping the flow of blood or secretions.

"No. 14, a laxative pill of value in relieving constipation, which is quite likely to be produced by the administration of the opium included in the list of medicines.

"Nos. 12 and 13, merely coverings for holding medicines in place, inactive medicinally.

"Nos. 6 and 10 are simple ointments.

"No. 7, hydrogen peroxid; a cleansing agent.

"No. 5. This preparation was originally thought to be a mild caustic, but has since been found and is now believed to be a non-irritant iodin preparation and cannot be used to destroy any kind of tissue.

"No. 2. Crystallized carbolic acid is a dangerous and pernicious substance in the hands of the layman. It is a corrosive poison and while decidedly a tissue destroyer it acts destructibly both on diseased and healthy tissue and, moreover, is liable to produce gangrene when applied to ulcerated sufaces.

"No. 3. Chromic acid in concentrated solution is well-known as a caustic and is used to some extent as such, but in the weak solution represented it is very doubtful if this result can be accomplished.

"No. 4. Concentrated acetic acid in the strength here represented is a strong escharotic and does destroy tissue, both diseased and healthy, and much care must be exercised in its use.

"No. 1. From the representations made at the hearing it appears that the company depends very largely for results on the preparations known as 'Red Ointment.'

"The analysis suggested that but little caustic effect could be expected and experiments were instituted with a view of confirming or refuting the claims made. The remedy was applied both moist and dry to normal tissues, with the result that after twenty-four hours' application little, if any caustic effect was noticeable. These experiments, therefore, show that this preparation, for which such remarkable claims were made, possesses but little virtue as an agent for the destruction of cancerous growth or tissue.

"In conclusion, this office is of the opinion that the nature of these remedies is such that they can not possibly effect a cure except by the merest chance. They are absolutely worthless for internal cancer. The claims, representations and promises employed in promoting this treatment are false and deceptive."

The Department of Agriculture also made an investigation of its own, and the chief inspector of the Bureau of Chemistry made the following statement regarding the "treatment":

"This treatment is sold as a cure for cancer. The words 'Cancer Cure' in the name of the company itself implies an ability to cure what is generally recognized as an incurable disease. The labels, correspondence, testimonials and other advertising literature of the concern are saturated with the idea that the treatment above described will cure cancer. As a matter of fact there is no drug or combination of drugs known at the present time which can be relied on with any degree of certainty whatever to effect a cure for cancer. The therapeutic effects of the ingredients of the remedies comprising this treatment have long been known to the medical profession, but notwithstanding this fact the best authorities make no claim to the ability to cure cancer by means of drugs."

CONCLUSIONS OF THE GOVERNMENT

The Assistant Attorney-General, in summing up his opinion of the whole matter, says: "The weight of medical authority is to the effect that cancer is a disease, the existence and character of which can only be reliably ascertained by a careful personal examination, and that a positive diagnosis always requires a competent microscopic examination. The Dr. Curry Cancer Cure Company's pretense that they can properly diagnose cases of cancer and prescribe remedies for them without personal examination merely by this correspondence scheme, is without any scientific or proven foundation, and they must well know that it is mere pretense. What is undoubtedly the fact that out of the many cases submitted to them and diagnosed by them as cancer there are some which are not cancer at all, but simply non-malignant sores which in some instances yield to treatment is what affords them a basis on the recovery of such cases to claim that they have cured cancer.

"According to the evidence submitted the medical profession knows of no drug or combination of drugs which can be relied on to cure cancer. That the Dr. Curry Cancer Cure Company has not succeeded where the profession has failed and that they are not honestly endeavoring to cure patients but that their pretensions to have discovered a cure for this disease are false and fraudulent and asserted merely to deceive and defraud suffering humanity, is revealed by the analysis of their medicines and the finding that they are merely ordinary antiseptics, narcotics and caustics.

"I find that this is a scheme for obtaining money through the mails by false and fraudulent pretenses, representations and promises, in violation of Sections 3929 and 4041 of the Revised Statutes, as amended, and recommend that a fraud order be issued against the Dr. Curry Cancer Cure Company and E. W. Ramsey, at Lebanon, Ohio."

The fraud order was issued.

Curious Pharmacologic Action of May-Pop (Passiflora Incarnata)

In perusing the "literature" of some of the fearfully and wonderfully made proprietary mixtures on the market one is uncertain whether the attitude of their manufacturers is "We aim to please" or one of "Heads we win, tails you lose." The uncanny elasticity of pharmacologic action in proprietaries of the type referred to is the cause of this uncertainty. For instance we find that both amenorrhea and menorrhagia are amenable to the same remedy and it is nothing unusual for a nostrum to be both a stimulant and a sedative.

We are reminded of this fact in perusing the "literature" of Daniel's Concentrated Tincture of Passiflora Incarnata, a proprietary marketed by J. B. Daniel, Atlanta, Ga. According to the booklet this remedy is to be employed in both convulsions and paralysis. Unlike many nostrums the proprietor claims to base his recommendations on exact pharmacologic investigations of which he produces two brands; the doubting physician pays his money and takes his choice. If he has a case of convulsion let him consult the laboratory report of Dr. Isaac Ott, who tells us that "in Passiflora Incarnata we have a drug of considerable power producing a depressant action on the reflex activity of the spinal cord." If, on the other hand, the physician has a case of paralysis to deal with he should turn over the page and take the authority of the certificate of the "Iamatological Bureau" which states, "it notably exalts the reflex function of the spinal cord."

Let the doctor in search of a hypnotic that is not a hypnotic and a powerful remedy that "does not endanger the heart" take his choice between these two contradictory actions. It is all the same to the nostrum maker so long as the doctor uses his "only reliable preparation of May-Pop" for all cases, every time and all the time.

But, seriously, isn't it about time that such opera bouffe methods of presenting medicinal agents to physicians should be resented by the medical profession? Disease itself is a serious thing and the treatment of disease is no trifling matter. The attempt to induce physicians to use a preparation by investing it with incongruously contradictory virtues neither flatters the intelligence of the medical profession nor invests pharmacy with any degree of dignity.

Correspondence

Notes on a Trip to South Africa

To the Editor:—Not the least of the many discussions relating to a better and more highly developed physique in man, has been one which has universally created a feeling of horror—I allude to the prevention of the continuation of life in a child deformed mentally or physically after its birth. It is not uncommon knowledge that the perfect development of the Zulus of Natal, and their superior mental capacity have far overtopped that of other native tribes of South Africa. Years before the advent of the white man in Natal it was a tribal dictate that infants with deformity or malformation of head or body should be destroyed immediately after birth. Students of heredity and of men will see the reason for the physical and mental development of the Zulu. A child born of healthy parents, with a perfect physical development, cannot but gain the mastery over the child born in tribes which do not observe any of the laws of the Zulus. With a healthy body and an equally healthy mind, it is natural that the Zulu should have sought healthy surroundings and follow Hygeia as he has done. Compare the Zulus of sixty and more years ago with those of to-day since the laws of Great Britain have suppressed the laws of the Zulus themselves. From a sober, moral and industrious race, they are hardly superior to-day to the other tribes. Their spirit of independence and consciousness of superiority is rapidly waning.

The question I have referred to I have not mentioned with a view to discussion, but simply because its significance struck me forcibly on a recent visit to South Africa. As native or tribal laws differ, so also do their customs. The contrast between Zulu and Bushman is indeed great, and contrary to the ill opinion we hold of the virtues of the Bushman, we cannot but wonder at the original meaning of the so-called Hottentot apron, really occurring in the Bushman and not in the Hottentots. The Hottentot, in civilization, is midway between a Kaffir and a Bushman. In a remarkable collection in the Cape Town Museum of life-size casts of several tribes of South Africa, there is a beautiful specimen of a Bushman woman in which the apron appears to the length of 2 inches or slightly more. The apron is the elongation of the labia minora. Just what means were employed to elongate it, so as to form a protection against any forcible entrance to the vagina, is not agreed on by authorities. Very little about it is known to-day, but it has been suggested to me by Mr. Lightfoot of the Cape Town Museum that weights of some kind were constantly worn in the younger years of Bushman maidens, instead of the stretching by pulling on the labia during the life of the woman.

Medical men who are leaning toward "healing by suggestion" may be interested in knowing that the art was practised in South Africa among the natives long before Bartholomew Diaz and Vasco da Gama discovered Southern Africa. Some years ago I had the opportunity of witnessing a native "doctor" endeavoring, apparently much against the will and consciousness of the patient, to suggest or persuade him that the ill and pain present were really misconceived and outside the body, and that he was well. The constant repetition by the "doctor" of the argument must through its monotony of sound put the patient to sleep and perhaps temporarily improve him.

Among the thousands of Kaffirs employed in the mines, the prevalence of syphilis is surprising. An institution of the government, similar to a quarantine smallpox station, was established to deal, apparently, with nothing else than syphilis. Not so very many years ago, syphilis was practically unknown among the natives of South Africa. Miners' phthisis is also increasing, and among the white miners it can almost be called a common disease. By far the majority of the inmates of that remarkable asylum for leprosy, near Pretoria, and also of that at Robbens Island, Cape Colony, are Kaffirs. Insanity is likewise common among the Kaffirs, especially those who are near large cities.

Ills which assail the Kaffir mentally and physically are numerous, and the old question of the moral and ethical value of civilization is again brought to mind.

A not uncommon curiosity among the natives is an affection in which the skin has a piebald appearance. The areas in which no pigment occurs change, so that the native presents a skin that is constantly adding or losing its pigment.

Blackwater fever, miners' anemia (ankylostomiasis), dysentery, malaria, smallpox and inflammatory affections of the eyes due to the pollen of blackthorn trees during the spring, are among some of the diseases which have a medical interest.

In conclusion, let me attempt to interest medical men in South Africa. Instead of hunting expeditions, have scientific expeditions for the study of these numerous tropical diseases which are rare in other parts of the world. South Africa contains more material than can be found anywhere else, and which will prove of undoubted value to the profession here.

James A. Honey, M.D., Cambridge, Mass.

Method of Increasing the Efficiency and Life of the Dry-Cell Battery

To the Editor:—Some years ago I began to seek for some method of increasing the life and efficiency of dry cells. I at first employed the usual methods (potassium permanganate and sal ammoniac solutions, etc.). These proving unsatisfactory, I at last hit on the following simple but cheap and satisfactory method:

When my dry battery has become exhausted, I take an ordinary $\frac{3}{8}$-inch drill-bit of sufficient length and drill a hole as near as possible to the carbon and between the carbon and the outside zinc covering. This hole should reach to within 1 inch of the bottom of the cell, beginning, of course, at the top or sealed part of the battery. I shake out of the cell all loose dust and particles, and place in this hole a $1\frac{1}{2}$-ounce glass funnel, having a stem not less than $1\frac{1}{2}$ inches in length, and of sufficient thickness to fit snugly, especially at the upper part of hole already prepared. This will prevent regurgitation of liquids to outside top of cell. Having secured the funnel firmly in the cell, I pour into it until three-fourths full (about an ounce) of chemically pure hydrochloric acid. This will start an immediate reaction and hydrogen and air bubbles containing particles of contents of the cell will regurgitate through the funnel and contents. It will require from eight to twenty-four hours for this reaction to be completed and the hydrochloric acid absorbed. Owing to a tendency for the small funnel to become clogged, it is necessary from time to time to pass a slender wire down through the funnel neck and hole in the cell. After absorption of the acid, I pour water in the funnel just as long as the cell will take it. When the cell has become thoroughly saturated inside, I seal it carefully with ordinary sealing-wax, set aside for twenty-four to forty-eight hours or longer, and test the cell for battery power. If the work has been carefully done, the results will not be disappointing.

I have in use in my office a battery of dry cells whose first efficiency was a life of three months, after which I treated them as above, and they have been in more or less constant use for a little over ten months. At present there is no sign of weakening or deterioration, and their regenerating ability is remarkable. How long they will last I am not prepared to say. They have exceeded my most ardent expectations. I have ceased discarding my old dry cells, and consider them more valuable after a renewal of this kind than when fresh from the hands of the manufacturer.

Edward M. Hanson, Keokuk, Iowa.

A Convenient Source of Carbon Dioxid Snow

To the Editor:—The treatment of certain dermatoses by carbon dioxid snow—a substitute originally suggested by Dr. Pusey for the less easily obtainable and less easily managed "liquid air"—has now an established place in the armamentarium of the dermatologist. Its common source is from the large cylinder of carbon dioxid furnished to soda-water fountains. This cylinder, although probably the cheapest source, is large, bulky, cumbersome and unsightly for office use, besides being somewhat clumsy for handling. I have recently found a convenient substitute for this; it is the small cylinder containing liquefied carbon dioxid sold for the inflation of a single automobile tire. It contains sufficient liquefied gas for a large tire—a sufficient quantity, as I have found, to produce enough "snow" for one average dermatologic application. This cylinder is about one inch in diameter and twelve inches in length; it costs $1, and when empty is returnable, being credited to the amount of 20 cents toward a new tube. Its manipulation, for either tire inflation or "snow"-making, requires a handle with valve and small hose attachment, which costs $2; this can, of course, be used indefinitely.

Henry W. Stelwagon, Philadelphia.

An Envelope Powder Shaker

To the Editor:—Many physicians and surgeons find it difficult to apply antiseptic powders to wounds properly. A powder blower that will apply the powder evenly, lightly and not wastefully, over the edges of wounds has not yet been offered to the public. Some surgeons use a pledget of cotton with dressing forceps, but this is unsatisfactory as it requires that the powder be poured out on a paper. I have used an envelope for a number of years with much satisfaction and a great saving of powder. It is used as follows: Place 15 or 20 grains of any powder, the finer the better, in an ordinary druggists' prescription envelope, which should then be sealed tightly and the tip of one of the corners torn off. Now take up the envelope between the thumb and fingers, gently press the sides so as to make a little air space and tap on the center of it with the tip of the index finger. This operation will blow out a very fine cloud of the powder and by holding it close to the wound it will take but a few taps with the finger to cover the wound with the finest coating possible. When a corner has been thus used it may, by using the handle of a knife, be turned down tight, and the next time another corner may be torn off, as the crimped corner interferes with the ejection of the powder. I have dressed many large wounds several times without using more than 15 grains of powder and one envelope.

S. A. Newman, M.D., Cassville, Mo.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HISTORY OF SEROTHERAPY

To the Editor:—I desire to obtain a history of serotherapy. Can you direct me to such a publication?

W. S. Devine, Marshalltown, Iowa.

Answer.—Dr. Ludvig Hopf's "Immunität und Immunisirung: Eine medicinisch-historische Studie," 95 pages, Tübingen, Franz Pietzcker, 1902, gives an excellent historical account of the theories of infection and immunity, including the development of serotherapy up to that date. The more recent developments are scattered through the literature. Wright's "Studies on Immunization," Constable, London, includes the main papers published by Wright on the opsonins, and contains about 500 pages. Sauerbeck's "Neue Tatsachen und Theorien in der Immunitätsforschung," published in 1907 in the Lubarsch-Ostertag Ergebnisse, and also as a separate monograph, by J. F. Bergmann, Wiesbaden, gives a thorough review particularly of the opsonins and aggressins (over 300 pages).

INJECTION TREATMENT FOR HEMORRHOIDS

To the Editor:—Kindly give list of works on the injection treatment for hemorrhoids.

L. A. W.

Answer.—We know of no special book on the injection treatment of hemorrhoids, but it is described in the standard works on rectal diseases, among which may be mentioned:

Agnew: Rectal Diseases, L. S. Matthews & Co., 2623 Olive St., St. Louis, Mo.
Allingham: Diseases of the Rectum, William Wood & Co., 51 Fifth Ave., New York.
Andrews: Rectal and Anal Surgery, Chicago Medical Book Co., Honoré and Congress Sts., Chicago, Ill.
Ball: Diseases of Rectum and Anus, W. T. Keener & Co., 90 Wabash Ave., Chicago, Ill. (This firm has gone out of business.)
Gant: Diseases of the Rectum and Anus. E. A. Davis Co., 1914 Cherry St., Philadelphia, Pa.
Goodsall and Miles: Diseases of the Anus and Rectum, Longmans, Greene & Co., 91-93 Fifth Ave., New York.
Kelsey: Surgery of the Rectum, William Wood & Co., 51 Fifth Ave., New York.
Mason: Office Treatment of Rectal Diseases. L. S. Matthews & Co., 2623 Olive St., St. Louis, Mo.
Mathews: Diseases of the Rectum, Etc., D. Appleton & Co., 436 Fifth Ave., New York.
Tuttle: Diseases of the Rectum, D. Appleton & Co., 436 Fifth Ave., New York.
Wallis: Surgery of Rectum, William Wood & Co., 51 Fifth Ave., New York.

These books can be obtained through medical booksellers generally.

Miscellany

SIMPLE REFRACTION FOR FAMILY PHYSICIANS

Its Promotion During 1908-09*

LEARTUS CONNOR, A.B., M.D.
DETROIT, MICH.

At its 1908 meeting the Michigan State Medical Society publicly initiated a movement "to qualify family physicians for the refractive work now in the hands of opticians." This paper aims to sketch briefly our progress.

By some oversight our medical colleges have rarely taught their students practical refraction, while they inoculated them with the idea that good refractive work was possible only to a specialist. Meantime, the science and art of refraction reached a high standard of perfection in the hands of specialists, working outside the colleges. Naturally, this standard was impossible to the average student or family physician, and a course adapted to their needs has not found its way into college curriculums. The course must be such that the student can master it without interfering with his other courses, and the family doctor practice it while caring for the other disorders of his patients. It will certainly include simple refraction, as then, by the aid of the specialist, in complicated cases, the refractive needs of all the people will be fully met.

Opticians began the practice of refraction, because ophthalmologists were too widely scattered and too high-priced; the family doctors were ignorant of simple refractive work and afraid to attempt its mastery. By organization and business push opticians so impressed the people to whom they prescribed and sold spectacles that sixteen state legislatures have granted them special rights, stolen from the medical acts, to practice that ophthalmology which family physicians should be practicing. They showed the legislatures that our system of medical education failed to provide physicians able to determine the refraction of the people's eyes. Our movement aims to promote such training of the family physician that he with the ophthalmologist will be adequate to care for the refractive needs of the people, and so to obviate the present necessity for optometrists.

The great obstacle to this movement is the wide-spread conviction that family physicians cannot master, much less practice, simple refraction. Yet it is in evidence that laymen have learned and do successfully practice this part of medicine; surely the physician's training should enable him to outstrip the layman in this competitive race, and it would if he made equal effort. Further, the evidence is overwhelming that family physicians have mastered simple refraction and are now successfully practicing it in connection with their other work. In my possession are many letters establishing this fact. Time admits the reading of but two, and these only in abstract.

The first letter is from Dr. Gerald Edmunds of Honor, Mich., and is dated May 2, 1909. He says:

"I think it may interest you to know that for some time I have tried to fit myself for 'general practice.' I graduated from the Chicago College of Physicians and Surgeons in 1892, and practiced in Chicago about eight years, when I located in this thriving little town. I used to have dreams of special practice as an 'unlimited practitioner,' but when I located in a small place, I found my time so occupied that it was all I could do to make a better practitioner of myself. After reading your article on the 'neglected patches' in the field of medical practice, I came to the conclusion that I had long neglected to fill the wants of my families, because I was not equipped to correct common defects of vision; besides, my son was troubled with a simple refractive error which I was incompetent to correct. So I bought Theobald on the Eye and Parker on Refraction (I already had Noyes), and spent my spare time in studying. I then bought from the Johnson Optical Company a small trial case and some fitting frames and went to work. I fitted my first patient the latter part of November, 1908, and since have determined the refraction in about thirty-five moderately simple cases, without any effort to push this as a specialty—simply having the paraphernalia for refraction about the office brought this work. I had formerly referred such cases to persons at a distance, much to the inconvenience of my patients. After this experience I am satisfied that any physician, with a reasonable amount of push, can add to his income, in a legitimate way, quite a few dollars during the year and benefit the public a great deal.

"I think that most physicians dislike the idea of being general practitioners, and feel that unless they at least claim a specialty the public will not think they amount to much. I am proud of being a general practitioner, and think that there is a great field for 'specializing' along the line of 'general practice.' The profession of medicine is too vast to be grasped in all branches, in all details, by one mind."

The second letter is from Dr. W. C. Garvin, of Millington, Mich., dated June 20, 1909. He says:

"I am enclosing herewith the program of the last meeting of the Tuscola County Medical Society, at which Dr. Hays told his personal experience in refraction, and the paper was very generally discussed. There are six physicians in Tuscola county now doing something along this line, and I think that the traveling optometrists will find poor picking in this section in the future.

Since Oct. 17, 1908, I have fitted eighteen people with glasses, and think that they have all been satisfied, even if I have not done every case to my own satisfaction. I learn something from each case in which I determine the refraction, and unless I can improve the vision do not order glasses. Thus far I have found no case in which I thought glasses were really needed, that I have been unable to relieve, but should I find such a case I will refer it to the nearest specialist."

The family physician refractive work reported in these letters and much more told in letters which time forbids reading, was stimulated by the unanimous passage by this society last year of the following preamble and resolutions offered by Leartus Connor and seconded by F. W. Robbins:

"WHEREAS, Michigan now has three classes of medical practitioners: viz.: (1) The family physician, (2) specialist, (3) and remnants, as opticians, osteopaths, Christian scientists, etc. (all persons devoid of adequate training for the duties of the physician);

"WHEREAS, Among those remnants are the optometrists, who live on the cases of refractive defects neglected by the family doctor, and without the specialists' field;

"WHEREAS, It is discreditable to the medical profession and harmful to the people that any part of medical practice fall into the hands of unqualified persons;

"WHEREAS, It being a physical impossibility for the fully trained ophthalmologist to care for all the neglected class, it remains for the family doctor to qualify himself to recognize and treat the simple cases, seeking expert aid as emergency demands, if the medical profession is to occupy its entire field. Therefore, be it

"*Resolved*, That the councilors of the Michigan State Medical Society be directed to take this matter up with their several county societies and so educate their constituents that between the family physician and ophthalmologist the needs of the people be fairly and fully met.

"*Resolved*, That the council request the Michigan State Board of Registration, (1) to place among its requirements for a license to practice medicine, a practical demonstration by the applicant of his ability to recognize and treat simple presbyopia, simple myopia and simple hyperopia; to recognize and treat the infectious diseases of the eye and the uveal tract; and (2) that it cooperate with our legislative and public policy committee in all practical efforts to prevent the enactment by the Michigan legislature of a law giving opticians the legal right to practice ophthalmology in Michigan."

These resolutions were the outcome of a comprehensive study of the entire subject during the preparation of a paper on "Ophthalmology for General Practitioners" read before the American Academy of Ophthalmology and Oto-Laryngology and published in THE JOURNAL (Nov. 28, 1908, li, 1833). The facts of the paper were granted by the academy, the action advised approved, but regarded as impracticable. It was hoped that the resolutions would awaken the profession to study the situation, and induce some to qualify themselves to practice simple refraction; our letters show that these hopes were in some degree realized.

Further, the subject was taken up with individual members of the Michigan State Board of Registration and on Feb. 12, 1909, the secretary, Dr. B. D. Harison, sent the following letter to medical colleges:

"I am directed by the chairman of the examination committee, who has full charge of the matter, under resolution of the board, that in the future, beginning with the next spring examination, all applicants for license will be required to demonstrate their fitness to do practical refraction work, in addition to the usual written paper on diseases of the eye, ear, nose and throat. The examination on this subject will be conducted by a specialist and will constitute an integral part of the examination, and failure to obtain 50 per cent. of possible standing will subject the applicant to refusal of license."

---

* Read before the Michigan State Medical Society, September, 1909

It is reported that on receipt of this notice many colleges, for the first time, began to teach their students simple refraction. Efforts are being made to have other state registration boards follow Michigan's example, and it is confidently expected that in the near future all who enter the practice of medicine will be able to do simple refraction. This requirement is definite, fair to the applicant, helpful to the profession, and beneficial to the people.

Besides the paper already mentioned, others were read before the Wayne and Tuscola county medical societies and the American Academy of Medicine. I also published in THE JOURNAL (April 10, 1909, lii, 1195) a letter giving in some detail reasons why family doctors should be able to do simple refraction.

Dr. Alvin A. Hubbell, of Buffalo, N. Y., in his address as chairman of the Section on Ophthalmology of the American Medical Association, June, 1909, discussed the "Ophthalmic Qualifications Which Should Be Demanded of the General Practitioner and of the Specialist Respectively" (THE JOURNAL, June 26, 1909, 2089). The committee appointed by the section to report on this address recommended the following:

1. "Every general practitioner should have the training in ophthalmology which will enable him to manage infectious diseases of the eye and its refractive defects. To obtain this qualification, medical colleges should make such training obligatory and state boards of registration demand it as a condition for license.

2. "Every general practitioner who desires to become an ophthalmologist should add to his training a comprehensive study of ophthalmology; do experimental work in the laboratory; and personal clinical experience in hospital or private office. To insure these qualifications, there should be appointed on each state board of registration at least one ophthalmologist, to examine applicants for license to practice ophthalmology.

3. "If these recommendations be approved by the Section, it is urged that a committee of three be appointed by the chair to study the subject and report their findings of the detailed measures necessary to secure trained family physicians, adequate for the needs of all the people, when suffering from ocular disabilities."

These recommendations were unanimously adopted by the Section, and the following committee appointed, viz.: Leartus Connor, Detroit; James Thorington, Philadelphia; and Albert R. Baker, Cleveland. It will be noted that future ophthalmologists will be asked to have the diploma required of the general practitioner, supplemented by a comprehensive study of ophthalmology, including experimental laboratory work and clinical experience in hospital or private office, all to be satisfactorily demonstrated to the satisfaction of the ophthalmological member of the state board of registration. As this Section numbers over eleven hundred members, the significance of its endorsement of these resolutions is apparent.

From evidence thus presented the proposition that "the family physician ought to be able to do simple refraction" has been endorsed by the Michigan State Medical Society; the American Academy of Ophthalmology and Oto-Laryngology; the American Academy of Medicine; the Section on Ophthalmology of the American Medical Association, and is required by the Michigan State Board of Registration as a condition for license to practice medicine.

By private letters, over signatures of their writers, it is shown that some family doctors have learned and are successfully practicing the art of simple refraction. It would be an insult to the other physicians in Michigan to suppose them inferior in this respect. Doubtless most are surfeited with practice and do not care to make the attempt, but if they tried they would surely succeed. Possibly the new men who enter the field will make the older ones take notice, as their patients leave them for the new doctor who can manage simple refraction.

At its meeting, June 14, 1909, the Tuscola County Medical Society listened to a paper by one of its members, a general practitioner, on "Some Points on Refraction," which was generally discussed by his fellow members, many of whom are earnest students of the subject. Similar incidents will occur in other counties, as a considerable number of their members master "simple refraction." Naturally this will lead to the mastery and discussion of other topics in general practice ophthalmology. This new line of society activity will augment the interest in and power of county societies, and so of the state society. As has occurred in Tuscola county, the opticians will lose their ophthalmic practice in the same proportion that family physicians become qualified therefor.

It is much that the largest ophthalmological society in America, the Section on Ophthalmology of the American Medical Association, has endorsed this movement and appointed a committee to encourage state registration boards to require a working knowledge of simple refraction as a condition for granting a license to practice medicine; and medical colleges to introduce it into their curriculums. So far as I am aware, this is the first special society to encourage the family doctor to advance his interests and that of his families by cultivating a neglected field allied to his own.

It counts for much that the Michigan State Board of Registration, in behalf of the people, demands a working knowledge of simple refraction as a condition for granting a license; because medical colleges must prepare their graduates therefor.

With results thus briefly sketched, gained during a single year, surely our council will be encouraged to more active effort in stimulating the members of their county societies (not surfeited with business) to master the technic of simple refraction.

All friends of the movement will be incited to greater activity and larger faith in its early triumph.

91 Lafayette Boulevard.

Symposium on Childhood Pathology

The pathology of childhood is discussed by various authors in the *Proceedings of the Pathological Society of Philadelphia*, September, 1909, xii, 3.

Antenatal Pathology.—B. C. Hirst deals with three problems in this subject, viz., antenatal syphilis, mechanically caused deformities, and the effects of maternal impressions. To prevent the fetus inheriting syphilis from a parent a period of four years under treatment should be insisted on. In a large proportion of cases syphilis acquired during pregnancy is transmitted to the fetus. The diagnosis of fetal or infantile syphilis can often be made without asking embarrassing questions by the discovery of the *Spirochæta pallida*, by Wagner's sign, by enlargement of the liver and spleen, by connective tissue overgrowth, skin eruptions, etc. Trauma or succussion in animals may lead to malformation of the fetus; and malformed or idiotic children may result from attempts to induce abortion. Violent emotion in the mother can affect the mentality of the child and can arrest its physical development or terminate its existence. But the photographic reproduction of some physical defect which the mother has seen is not to be expected, and such belief on the part of the laity should be combated by the physician.

Infections of the New-Born.—These are described by S. McC. Hamill. Mild infections of the umbilical stump are common. Omphalitis may extend along the arteries, usually starting with a periarteritis which spreads through the walls of the vessel, producing thrombi. The clots may break down and be converted into pus. The infection less frequently involves the veins and may extend to the peritoneum or liver, eventuating in sepsis of the new-born. Hamill regards melena as a symptom of septic infection. Septic infections in infancy may be due to streptococci, staphylococci, gonococcus, pneumococci, the colon bacillus, and many others. Contrary to the general supposition, Hamill believes that the new-born possess relatively high resisting power, or else infections would be more frequent, considering the numerous exposures to infecting agents. Infection may occur through the cord, the skin, the alimentary or respiratory tract, etc. The occurrence of a suppurating lesion of the cord does not prove it to be the portal of entry, as this infection occurs frequently without generalization. Infection through the skin may arise through the bath-tub, so that the use of sterilizable bath-tubs becomes a matter of importance. The care of the mouth, nostrils and anus is especially important to ward off infection through these channels. The pathologic changes are, briefly, congestion, hemorrhage and parenchymatous degeneration. Hemorrhages are especially important and may occur in the brain, lungs, pericardium, pleura, mucous membrane, etc. The liver usually shows the most marked changes such as parenchymatous or fatty degeneration, hepatitis and multiple abscesses. The kidneys may be the seat of parenchymatous changes, fatty degeneration, hemorrhages and interstitial inflammation. The pelvis is sometimes involved.

Status Lymphaticus.—This is the subject of a communication by J. Howland. The normal size of the thymus is undetermined, and, although investigation indicates the presence of a condition known as status lymphaticus in which the thymus and the lymphoid tissues are greatly enlarged and in which sudden death from cardiac syncope is very liable to occur, none of the theories so far advanced is sufficient to account for death in these cases. Mechanical pressure may be a factor in a small proportion of cases, but the supposition of a toxic action from the thymus is negatived by Howland's experiments. The theory that the thymus enlarges from a compensatory effort to supply the place of other organs is attractive, but attempts to explain it by lymphoid exhaustion in the spleen or glands are not successful, for the thymus does not exhibit a lymphoid structure, but is rather an epithelial organ. Twenty years after the enunciation of Paltauf's views we find ourselves still without a satisfactory explanation for death in status lymphaticus, but discarding vague theories enables us to get a clearer perception of where we stand.

Tumor Growth in Childhood.—This, according to David Riesman, cannot be determined by exact statistics. Such as are available indicate it to be relatively infrequent. Connective tissue tumors are more common than epithelial. If the tumor is malignant it takes the form of sarcoma rather than carcinoma. Of benign tumors fibroma, lipoma, chondroma, osteoma and myoma are uncommon or rare, while angioma and neuroma are comparatively frequent. Angioma is nearly always congenital or develops during the first year. It has been attributed to trauma, either intrauterine or at birth. Neuroma has its favorite site in the region of the eye. It usually takes the form of the plexiform neuroma, which in look and feel suggests a collection of earthworms under the skin and has a slow but progressive growth. Sarcoma is by far the most common tumor of childhood, all varieties being represented and the sites in the main being the same as in adult life. Sarcoma of the brain, including gliosarcoma, is the most frequent of brain tumors. In the internal organs, aside from the brain, sarcoma is rare, but frequently congenital. Congenital sarcoma of the liver and of the suprarenal gland has been reported by Pepper, who has collected five cases, and has also reported eleven cases of primary sarcoma of the suprarenal gland. A prominent symptom of these tumors is hemorrhage. Tileston and Wolbach have described as a clinical entity a peculiar primary sarcoma of the suprarenal gland which is associated with sarcoma of the cranium. The symptom that usually first attracts attention is the exophthalmus.

Chloroma.—Riesman considers this as a variety of sarcoma. It is a greenish-colored tumor occurring in the temporal and parietal region of the skull, the hard palate, the sternum and ribs, rarely in the skin. It is almost confined to children under the age of 15 years and is vastly more frequent in the male than in the female sex, the proportion being 36 to 10. The course is acute (four to six months) and the most striking symptom is exophthalmus, as it is also in the condition described by Tileston and Wolbach. Histologically, two types of chloroma may be distinguished, one in which the cells are large and lymphocytic, similar to those found in acute lymphatic leukemia; and one in which the cells resemble the myelocytes. These features have led Dock, Warthin and others to the view that chloroma is really a form of leukemia and not a tumor in the strict sense. The nature of the green color from which the tumor takes its name has not been definitely determined, but it is supposed to be due to the compactness of the highly granular cells.

Mixed Tumor.—An important and common new growth in childhood is the so-called mixed tumor, which passes under many names in the literature, such as sarcoma, carcinoma, myxosarcoma, rhabdomyoma, adenosarcoma, etc. The principal seats are the kidney, the ovary and the testicle. The growth of the tumor is rapid in contradistinction to that of hypernephroma, which is slow. Metastasis is not common, occurring in about 30 per cent. of the cases, chiefly to the lungs and liver. A curious feature of the tumors is that they do not directly involve the substance of the organ in which they are found, but press it aside. This is particularly noteworthy in the kidney. The surface of the section may be soft or gelatinous; at times it shows lobulation. Necrosis and hemorrhagic softening are common. The histologic structure is complex; striped and smooth muscle tissue, cartilage, adipose, mucoid, and elastic tissue, as well as glandular elements are found. In a rare case, reported by Muus, epidermal elements in the form of pearly bodies were present. The complexity of the tumors has given rise to a number of opinions as to their origin. Without going deeply into the subject it may be stated that the most acceptable view is that they are derived from a misplaced blastomere.

Retarded Mental Development.—D. J. McCarthy contributes a special study of this subject. The nervous tissues may show gross pathologic lesions or a practically normal nervous system. While alcohol and syphilis figure in the heredity, the important influence appears to be condition of lowered nutrition mainly due to tuberculosis. An additional clinical factor is the effect of prolonged and difficult delivery. The probable influence of the adrenals, pituitary, thyroid, etc., on cerebral development has been shown by modern investigations. In later childhood McCarthy has in two cases noted the connection of a persistent and enlarged thymus with a hallucinatory, delusional condition, lasting over several days with reflex dysphagia. In adult life, a grave neuromuscular condition, myasthenia gravis, is associated with and probably caused by the pathologic changes secondary to a persistent thymus. Instances have been noted in which the ganglion cells, in consequence of the presence of hemosiderin, underwent a change of function by which they became eliminators of the foreign substance and ultimately degenerated and became calcified. Such changes of function may be induced by congestion and edema, which may produce microscopic hemorrhages. In the minor grades of osmotic hemorrhage, due to prolonged passive congestion, perversion of function of the ganglion cell results without gross lesions. McCarthy believes that free blood in the tissues leads to that interference of function and potential which is manifested in later childhood in the failure to advance in mental development beyond a certain stage. Both experimental and clinical evidence show that microscopic blood osmosis with iron infiltration may exist both in the prenatal and postnatal states. That either inherited or acquired weakness or pathologic lesions of the vascular system would necessarily play an important part in the production of the above conditions is evident. The influence of tuberculosis and other dyscrasic states, syphilis, etc., could easily act in this way by leading to obstruction or rupture of capillaries or veins from increased pressure. This cause may not be the only one, but as an important factor in a large group of cases it deserves careful investigation.

Pasteurized Milk in Infant Feeding.—Physicians who have had large experience in the care and feeding of infants have a prejudice against the use of heated milk for prolonged periods. While it is admitted that the use of heated milk greatly diminishes the amount and seriousness of infantile diarrheas, it has been noted that while the children at first do well, later they may become flabby and anemic and the subjects of scurvy. Whether it is the heating or some other factor in the milk that induces scurvy is not determined.—M. J. Rosenau, in *Annals of Medical Practice.*

Association News

NEW MEMBERS

List of new members of the American Medical Association for the month of September, 1909:

ALABAMA
Pettey, F. P., New Decatur.
Winters, J. S., Bessemer.

ARKANSAS
Wall, E. D., Park Place.

CALIFORNIA
Bell, H. D., Oakland.
Blair, J. C., San Jose
Dozier, Earnest, San Francisco.

COLORADO
Horn, W. L., Boulder.

CONNECTICUT
Bill, P. W., Bridgeport.

DISTRICT OF COLUMBIA
Lowe, T. F., Washington.

GEORGIA
Corson, E. R., Savannah.
Gilbert, W. L., Atlanta.
Harrold, C. C., Macon.
Longino, L. P., Milledgeville.
McAfee, J. C., Macon.
Murphey, C. E., Atlanta.
Palmer, S. B., Macon.
Person, W. E., Atlanta.
Sterling, A. W., Atlanta.

ILLINOIS
Allison, C. N., Canton.
Bachmann, A. S., Forest Park.
Baker, G. J., Herrin.
Black, G. C., Table Grove.
Brinckerhoff, C. E., Chicago.
Drake, W. D., Aviston.
Drozdowitz, Theo., Chicago.
Escher, F. H., Chicago.

Book Notices

AMERICAN ILLUSTRATED MEDICAL DICTIONARY. By W. A. Newman Dorland, A.M., M.D., Assistant Obstetrician to the University of Pennsylvania Hospital. Edition 5. Flexible Leather. Pp. 876, with 2000 new terms. Price, $4.50 net. Philadelphia: W. B. Saunders Co., 1909.

The fifth edition of this useful dictionary contains thirty-eight pages more than its predecessor did. According to the preface to the fifth edition, "more than 2,000 new terms have been added. *The majority of these words appear for the first time in any dictionary.* Moreover, the entire book has been revised, and many of the definitions have been rewritten and improved. A special feature has been made of those words in the realm of biology which occur so frequently in the literature of physiology and pathology." These improvements are indeed commendable; but we must confess that no medical dictionary appears as yet to give adequate attention to this rapidly growing division of the medical vocabulary. We should have been glad, for instance, to have had the names given of the various species of mosquitoes which act as hosts to pathogenic germs. Moreover, we feel that the medical lexicographer who shall attempt to cover thoroughly the field *of those apparently indispensable plagues of medical literature*, eponymic terms, old and new, especially in pathology, anatomy and biology, will earn the gratitude of all users of medical dictionaries.

We regret that neither editor nor publisher has thought it worth while to make this dictionary a guide to capitalization. We hope they may see fit to remedy this defect in the next edition.

THE MALARIAL FEVERS [illegible] ND THE BLOOD PROTOZOA OF MAN. By [illegible] otain, Medical Corps, U. S. Army. Cloth [illegible] Price, $4.50. New York: William Wood & Co., 1909.

In this work Craig endeavors to present the important advances and facts of interest to the student and clinician in regard to the malarial fevers and related subjects. Craig has had a large personal experience in the United States military hospitals in this country, Cuba and the Philippines. He is well-known because of the importance of his investigations in malaria and other protozoan diseases, which, taken in conjunction with his exceptionally large and varied active clinical experience, renders him especially well-qualified to write a book of this kind.

The 360 pages devoted to the consideration of the malarial fevers is divided into five parts: (1) the etiology, (2) the general and special pathology, (3) the symptomatology and clinical varieties, (4) the sequelæ, complications and prognosis, and (5) the diagnosis, prophylaxis and treatment of the malarial fevers. There are three colored plates, drawn by the author himself, illustrating various stages in the development of the different kinds of malarial plasmodia, numerous photomicrographs and clinical charts. In addition to the thorough consideration of the malarial fevers from the clinical as well as the laboratory side, chapters have been added treating on hemoglobinuric fever and the blood protozoa of man. Like Manson, Sambon and others, Craig holds that hemoglobinuric fever is a separate disease caused by a hitherto undiscovered organism, and he advocates with much force and soundness that the disease should be studied so far as possible without bias by preconceived ideas as to its malarial nature. The fact that hemoglobinuric fever occurs in malarial regions and often complicates malarial disease, renders it necessary to include its consideration in a complete work on malaria.

The last four chapters are devoted to the Leishman-Donovan bodies, the cause of tropical splenomegaly; *Trypanosoma gambiense*, the cause of sleeping sickness; the spirochetes causing the relapsing fevers; and *Histoplasma capsulatum* of Darling. This part is illustrated by a plate, the omission of part of the lettering of which may be noted.

At the end of each chapter of the book is a list of the most important papers bearing on the particular subject discussed, with authors' and general index at the end. The book is clearly written; it bears abundant evidence of its author's first-hand knowledge and thorough scientific study of malaria; and it is believed that it will be accepted by English-speaking physicians as a standard treatise on the malarial fevers. Craig has rendered a valuable service in placing within reach of physicians needing it—and this is true especially of those in tropical and subtropical countries—this excellent and complete guide to the diagnosis and treatment of malarial and other protozoan diseases. It is a worthy continuation in its sphere of the fine American work in the field of malaria and protozoon diseases in which Dr. Craig has taken a prominent part for several years; and it reflects credit on the Medical Corps of the U. S. Army.

A SYSTEM OF OPERATIVE SURGERY. By Various Authors. Edited by F. F. Burghard, M.S., F.R.C.S., Teacher of Operative Surgery in King's College, London. In Four Volumes. Vol. 1. Cloth. Pp. 751, with illustrations. Price, $10. New York: Oxford University Press, 1909.

The rapid advances in operative technic made within the last few years have demanded constant revision of operative surgeries which are already on the market, or the publication of new ones. The field has become so vast that it is practically impossible for one man to cover the entire field of operative surgery in all its details satisfactorily. The aim of this work, the first volume of which is under consideration, is to secure the best in each separate line by delegating the subject-matter to men who are recognized as leaders and original workers in the subject assigned to them. The result is noteworthy, as all the chapters are good and there is a symmetry about the entire volume which is usually wanting in a system of either surgery or medicine.

The chapter devoted to disinfection of the hands and patient's skin is good. The simple technic of water, soap, 70 per cent. alcohol, and a mercury preparation is preferred. The technic advised follows very closely that given by Fürbringer. We do not agree that the nails should be cut as short as possible, for a nail of moderate length certainly affords the greatest protection to the thin cuticle beneath, and sterilization is much more easily performed when this cuticle is intact than when it is fissured, as is apt to be the case when the nail is cut as short as possible. The writer in this chapter does not, we believe, insist strongly enough on the use of rubber gloves. The statement that they are undesirable for some operations because they interfere with the sense of touch and because they are so slippery will not be confirmed by many. If gloves are used often, one becomes accustomed to them and certainly the results following their use can not be equaled by any chemical method of hand sterilization, none of which will stand a thorough bacteriologic test.

Chapter 1 of Section 2, dealing with infiltration and regional anesthesia, and embodying most of the excellent and well-known work of Mr. Barker, can be read to advantage by every one using local anesthesia.

In Section 3, devoted to amputations, the indications and contraindications are stated clearly. We think, however, that the value of conservative operations on myeloid sarcomas might have received more attention than it has on page 64. The dangers of shock during amputation and methods of preventing the same are discussed on page 69 in a very satisfactory manner.

The subject matter in this volume is presented very clearly; many useless details emphasized in other text-books of operative surgery are slighted in this for the broad, general principles, so that each page is filled with essentials.

The first volume of this work should presage a large circulation for the entire system. The names appearing in the list of contributors speak for its scientific value and the succeeding volumes will be awaited with great interest.

SYMPTOMS AND THEIR INTERPRETATION. By James Mackenzie, M.D., M.R.C.P., Physician to the West End Hospital for Nervous Diseases, London. Cloth. Pp. 297. Price, 7 shillings 6 pence. London: Shaw & Sons, 8 Fetter Lane, E. C., 1909.

This contribution by McKenzie is designed to assist in placing Medicine in that position in science which ought of right to belong to her, and to make it less possible for skilled surgeons and diagnosticians to give widely divergent opinions as to the nature of a complaint in some single individual. After an introduction in which Mackenzie emphasizes the importance of accuracy of observation and correctness of method—which, of course, must be based on exact knowledge of anatomy and physiology—the bulk of the work is devoted to analyzing symptoms as they are to be found in practice and emphasizing the misleading and reflex character often assumed. Mackenzie closes by calling attention to the necessity of interpreting the symptoms found, in relation to the body as a whole, and to the particular patient in hand. It is only by bearing in mind every source from which a given symptom may arise that the physician can guard against some unfortunate oversight which may mean only a delay in proper diagnosis or perhaps a more serious result.

To a considerable extent, the work is taken up with the subject of pain and an analysis of what it means in its various presentations; pain being, perhaps, the most common symptom for which the medical man is consulted. The work is not a reaction against laboratory methods of diagnosis, but a very timely contribution out of the ripe experience of a master, which will, if studied, certainly aid the practitioner in developing that far-seeing eye that looks through the oft-conflicting evidence of disease to the ultimate cause.

The book has one disadvantage in having been printed on heavy glazed paper, which was not necessary since the pictures do not require it. We recommend a light-weight paper for the next edition, so that the book may be light and more easily handled. The index, we think, could be expanded a little to advantage.

A TEXT-BOOK OF MATERIA MEDICA, PHARMACOLOGY AND THERAPEUTICS. By George F. Butler, A.M., Ph.G., M.D., Professor and Head of the Department of Therapeutics, Chicago College of Medicine and Surgery. Sixth Edition. Cloth. Pp. 708. Price, $4. Philadelphia: W. B. Saunders Co., 1908.

This, the sixth edition of Dr. Butler's book, contains but few changes from and additions to the previous edition; those that have been made, however, add to its value. In the new edition we find grindelia classed as a "Motor Depressant," balsam of Peru under the "Aromatic Acids," tar and balsam of tolu as "Drugs Acting on the Respiratory Membranes," while buchu, uva ursi, juniper, copaiba, oil of santal, cubeb and sabal are found under "Drugs Acting Particularly on the Kidneys." In the previous edition all of these drugs were lumped together under the "Group of Aromatics Used Particularly to Stimulate the Mucous Membranes of the Genitourinary or Respiratory Tract." The new arrangement is obviously more rational. We also find that opium, which in the fifth edition was classed under "Hypnotics," is now found more correctly under the "Narcotics." A brief but clear-cut exposition on opsonins and vaccine therapy has been added to the chapter on "Organotherapy." In discussing the probability of a serum therapy for syphilis we read: "The most recent work . . . would seem to show that a spiral organism, *Spirochæta pallida*, bears some relationship to the disease." In the light of our present knowledge of the relationship of the pale spirochete to lues this statement is conservative almost to the point of obsolescence. The arrangement of the book is good looked at from the standpoint of either the undergraduate or the practitioner; the idea of giving the name of each drug in English and in both the nominative and genitive (or in some cases accusative) Latin is an excellent one and should prove a valuable help to the prescription-writer. The chapter on prescriptions which deals with the combination of drugs, incompatibility, antagonism, estimation of amounts, grammatical construction of prescriptions and abbreviations of much-used words and phrases, will be of interest to those physicians—and their number is increasing—who take a pride in accurate and scientific prescribing.

A SYSTEM OF MEDICINE. By many writers. Edited by Sir Clifford Allbutt, K.C.B., M.A., M.D., LL.D., D.Sc., F.R.C.P., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, and Humphry Davy Rolleston, M.A., M.D., F.R.C.P., Senior Physician, St. George's Hospital. Cloth. Pp. 969, with illustrations. Volume V. Diseases of the Respiratory System, Disorders of the Blood. Price, $6 net. New York: The Macmillan Co., 1909.

The standard of Volume V of this series is equal to that of the previous volumes. Its contents embrace an article by H. Mackenzie on the "Physical Signs of the Lungs and Heart;" "Artificial Aerotherapeutics," by C. T. Williams; "Asthma and Hay Fever," by Goodhart and E. I. Spriggs; "Bronchitis," by William Ewart; "Pneumonia," by Beddard, Eyre and Fawcett; "Abscess and Gangrene," by J. J. Perkins, and "Pulmonary Tuberculosis," by Kidd, Bulloch and Bardswell. A. E. Wright, Allbutt, Hutchison, Garrod, French, Muir and S. Mackenzie are some of those who take part in the discussion of the disorders of the blood. The affections of the pleura, mediastinum and thymus are also considered. Needless to say, the entire copy of the previous editions has been revised and rewritten with the view to making this system authoritative. We commend particularly the splendid list of references appended to each subject, which can not fail to prove of value to every student of medicine.

ESSENTIALS OF LABORATORY DIAGNOSIS. By Francis Ashley Faught, M.D., Director [illegible] the Department of Clinical Medicine, Med[illegible] Philadelphia, Pa. Cloth. Pp. 309, with [illegible] 1.50. Philadelphia: F. A. Davis Co., 1909.

This little manual aims to provide a working outline for clinical laboratory methods, which shall be complete enough for the average student and brief enough for the busy practitioner. In general, this purpose is well achieved, and in spite of Dr. Faught's determination not to "burden the reader with unnecessary detail," he has managed to include a great many helpful practical suggestions, although the clinical interpretation of results must, in a work of this size, be treated very lightly. The chapter on urine is the best in the book, and is especially good, presenting both the theoretical and the practical sides in a complete and available form. The chapter on bacteriology, also, is good, though brief, and gives not only rules for identifying various bacteria, but methods of preparing culture media, sterilization, etc. The chapter on blood is unsatisfactory. The examination of the stained specimen does not receive the attention it merits, and the enumeration of leucocytes is dismissed rather summarily. No plates accompany this part of the work. The chapter on serum reactions and bacterial vaccines shows a lack of practical experience with these methods, and an insufficient appreciation of the difficulties and uncertainties of such procedures. The book is fairly well, but not profusely, illustrated, and contains a valuable appendix giving formulas for stains and other solutions in common use in the laboratory.

LEHRBUCH DER MAGENKRANKHEITEN FÜR AERZTE UND STUDIERENDE. Von Dr. H[illegible] für Magen und Darmkrankheiten in Ber[illegible] with illustrations. Price, 12 marks. Berlin: Verlag von S. Karger, 1909.

The work of Dr. Elsner will be especially welcome to those who have become somewhat acquainted with the results of modern research in the department of diseases of the stomach. Physiologic experimentation has gone far enough to establish facts regarding the functions of the stomach that are of wide-reaching applicability and must materially alter the treatment of these diseases. The developments of the last few years have placed in the hands of the practitioner in the large cities and in many of the smaller towns a means of diagnosis, the *x*-ray, which enables the form, position and motor functions of the stomach to be ascertained with a degree of exactness which leaves little to be desired. The results of the modern diagnostic aids form a special feature of the book. The great importance of functional diseases of the stomach is shown by the fact that they form a majority of the cases presenting themselves to the general practitioner and even to the specialist, and it is of great importance that their nature should be clearly recognized. To Stiller is doubtless due in a very large degree the credit of having demonstrated the constitutional and congenital nature of many of these affections. Elsner has clearly recognized the importance of Stiller's teaching and has presented it in a way that will be appreciated by his readers. The book is constructed on the usual plan, consisting of a general and a special part. Theoretical questions and historical matters have in the main been omitted, the space being given to subjects of more practical importance. The presentation of the subject is clear and methodical. The book is well illustrated. It is to be hoped that an English translation will soon appear.

EIGHTH ANNUAL REPORT OF THE WORK OF THE CANCER LABORATORY OF THE NEW YORK STATE DEPARTMENT OF HEALTH. Conducted at the Gratwick Research Laboratory, University of Buffalo. 1907, Paper. Pp. 59.

This report presents several features of interest to all who appreciate the importance of the cancer problem. The director, Dr. Gaylord, has taken the opportunity to review the course and achievements of cancer research in the last decade, which practically covers the existence of the New York Cancer Laboratory, and shows that the advance in this sphere of knowledge, to which his laboratory has made important contributions, has substantially confirmed the theory of the infectivity of cancer to the support of which the early efforts of the laboratory were especially devoted. Several recent observations indicate that this theory will soon bear practical fruit. The discovery of cage infection, and the report of small endemics of animal cancer, as well as the peculiar grouping brought to light by a study of the geography of human cancer, indicate a contagiousness of the disease which makes a certain amount of isolation prudent if not imperative. The discovery of spontaneous cure of mouse tumors and of the power of the blood of normal animals, and especially of convalescents from cancer to destroy the infectivity of cancer cells, give promise of an eventual application to the cure of human cancer.

The article of Gary N. Calkins on "Rhythms of Growth Energy in Mouse Cancer," affords a good insight into the present status of the theory of the pathogenesis of cancer. The cancer cell differs from an embryonic cell in that it shows no power of adaptation, correlation or differentiation and from the ordinary epithelial cell in the possession of an extraordinary vigor of growth and the character of infectivity. These it owes to something within itself. Its parasitic character appears to be inseparable from its cellular existence and must be assumed to be due to the action of some special stimulus. This stimulus is believed to be a micro-organism, perhaps of ultramicroscopic size.

The paper by Dr. Gaylord on spirochetes accompanying cancer indicates a close relationship between these organisms and the growth of cancer. It is suggested that they may act by preparing the soil for the real infecting agent. An interesting fact recorded in the review of the work for 1907 is the discovery of a breeding establishment for mice where cancer is endemic. About 63 tumors have developed in approximately 7,000 mice reared at this place in eighteen months. The introduction of the breeding of white rats has proved that the place is as favorable for the growth of tumors in these animals as in mice. The tumors were mostly cancers of the female breast.

The Public Service

Medical Department of the Army

Changes for the week ended Oct. 2, 1909:

Stephenson, Wm., lieut. col., ordered to Fort Leavenworth, Kan., for duty, on expiration of his present leave of absence.

Davidson, W T., capt., relieved from duty on the transport *Buford*, and ordered to Columbus Barracks, Ohio, for duty.

De Loffre, S. M., capt., when relieved from duty at Columbus Barracks, Ohio, ordered to Fort Bliss, Tex., for duty.

Manly, C. J., major, when relieved at Fort Bliss, Tex., ordered to Fort Douglas, Utah, for duty.

Bevans, J. L., capt., granted leave of absence for 10 days.

Cowles, C. D., Jr., 1st lieut., relieved from duty in the Philippines Division, and ordered to duty on the transport *Logan*.

Raymond, T. U., major, McLellan, G. H., Mueller, Armin, Frock, C. E., 1st lieuts., relieved from duty at their present stations, and ordered to San Francisco, Cal., to sail December 6, for Philippine service.

Buck, C. D., capt., Rukke, G. V., King, Edgar, 1st lieuts., relieved from duty in the Philippines Division; will sail December 15, for San Francisco, Cal.

Tasker, A. N., 1st lieut., relieved from duty in the Philippines Division, and ordered to duty on the transport *Sheridan*.

Frick, E. B., major, granted leave of absence for 15 days.

Foley, T. M., M. R. C., relieved from duty at Fort Moultrie, S. C., and ordered to Henry Barracks, P. R., for duty.

Drake, P. G., Henry, Z. L., Wiggin, D. C., Bailey, Edward, M. R. C., relieved from duty at their present stations, and ordered to San Francisco, Cal., to sail December 6, for Philippine service.

Bowen, A. G., Crum, W. H., Fletcher, J. P., Holmes, R. W., M. R. C., ordered to active duty; will proceed to Washington, D. C., for a course of instruction at the Army Medical School.

Simpson, J. A., M. R. C., ordered to active duty, will proceed to the Presidio of Monterey, Cal., for duty.

Bundesen, H. N., M. R. C., ordered to active duty, will proceed to Fort D. A. Russell, Wyo., for duty.

Medical Corps of the Navy

Changes for the week ended Oct. 2, 1909:

Von Wedekind, L. L., surgeon, ordered to the Naval Recruiting Station, Chicago, Ill.

Schmidt, L. M., asst.-surgeon, detached from the Naval Recruiting Station, Chicago, Ill., and ordered to the navy yard, Charleston, S. C.

Shippen, L. P., asst.-surgeon, detached from the Navy Yard, Mare Island, Cal., and ordered to Washington, D. C., and report at the Bureau of Medicine and Surgery, Navy Department.

Diehl, O., medical inspector, ordered to duty on board the *Charleston*, as fleet surgeon, 3d squadron, Pacific Fleet.

Davidson, A. B., [illegible])ointed Acting Assistant Surgeon, with ran [illegible] grade) from Sept. 27, 1909; ordered to [illegible] Medical School, Washington, D. C.

Minter, J. M., asst.-surgeon, detached from the Naval Recruiting Station, Pittsburg, Pa., and ordered to the Naval Hospital, Norfolk, Va.

Straeten, R. J., asst.-surgeon, detached from the Naval Hospital, Guam, M. I., and ordered to the *Supply*.

Toulon, A. J., asst.-surgeon, detached from the *Supply* and ordered to the Naval Station, Guam, M. I.

Public Health and Marine-Hospital Service

Changes for the seven days ended Sept. 29, 1909:

Bailhache, P. H., surgeon, on leave, detailed for duty on Revenue Cutter *Seminole*, Sept. 25 and 29, and Oct. 1, 1909, in connection with the Hudson-Fulton Celebration.

Wasdin, Eugene, surgeon, granted 1 month's leave of absence from Sept. 22, 1909, on account of sickness.

White, J. H., surgeon, granted 14 days' leave of absence from Sept. 25, 1909.

Sprague, Ezra K., surgeon, granted 16 days' leave of absence from Oct. 8, 1909.

Lavinder, C. H., P. A. surgeon, detailed to represent the Service at the annual meeting of the Mississippi Valley Medical Association, to be held in St. Louis, Mo., Oct. 12-14, 1909.

Moore, Dunlop, P. A. surgeon, Bureau order of Aug. 7, 1909, revoked, directed to proceed to San Francisco, Cal.

Holt, John M., P. A. surgeon, granted 1 month's leave of absence from Aug. 16, 1909.

Wille, C. W., P. A. surgeon, granted 7 days' leave of absence from Sept. 26, 1909.

Warren, B. S., P. A. surgeon, detailed to represent the Service at the annual meeting of the Mississippi Valley Medical Association, to be held in St. Louis, Mo., Oct. 12-14, 1909.

Boggess, J. S., P. A. surgeon, granted 7 days, leave of absence from Sept. 24, 1909, under paragraph 191, Service Regulations.

Collings, G. L., P. A. surgeon, detailed for duty on Revenue Cutter *Androscoggin*, Sept. 25 and 29, and Oct. 1, 1909, in connection with the Hudson-Fulton Celebration.

Herring, R. A., asst.-surgeon, detailed for duty on Revenue Cutter *Mohawk*, Sept. 25 and 29, and Oct. 1, 1909, in connection with the Hudson-Fulton Celebration.

Krulish, E., asst.-surgeon, detailed for duty on Revenue Cutter *Gresham*, Sept. 25 and 29, and Oct. 1, 1909, in connection with the Hudson-Fulton Celebration.

Wood, C. E., asst-surgeon, granted 7 days' leave of absence from Sept. 28, 1909, under paragraph 191, Service Regulations.

Stiles, Charles W., chief, Division Zoology, Hygienic Laboratory, detailed to attend the annual meeting of the Mississippi Valley Medical Association, to be held in St. Louis, Mo., Oct. 12-14, 1909.

Bready, J. E., acting asst.-surgeon, granted 7 days' leave of absence from Oct. 5, 1909.

Gochicoa, A. E., acting asst.-surgeon, granted 30 days' leave of absence from Sept. 12, 1909, 25 days with pay and 5 days without pay.

Goldsborough, B. W., acting asst.-surgeon, granted 1 day's leave of absence, Sept. 30, 1909, without pay.

Horning, Henry, acting asst.-surgeon, granted 15 days' leave of absence from Oct. 4, 1909.

Naulty, C. W., Jr., acting asst.-surgeon, granted 1 day's leave of absence, Sept. 25, 1909.

Terry, M. C., acting asst.-surgeon, granted 21 days' leave of absence from Oct. 1, 1909, with pay, and 9 days from Oct. 22, 1909, without pay.

Underwood, F. R., acting asst.-surgeon, granted 22 days' extension of annual leave from Aug. 23, 1909, on account of sickness.

PROMOTIONS

Assistant Surgeon Hugh de Valin, commissioned a P. A. Surgeon (recess), to rank as such from Sept. 21, 1909.

Assistant Surgeon Marshall C. Guthrie, commissioned a P. A. Surgeon (recess), to rank as such from Sept. 9, 1909.

Health Reports

The following have been reported to the Public Health and Marine-Hospital Service, during the week ended Oct. 1, 1909:

SMALLPOX—UNITED STATES

District of Columbia: Washington, Sept. 11-18, 2 cases.
Illinois: Danville, Sept. 11-18, 1 case.
Massachusetts: Boston, Sept. 11-18, 1 case.
Missouri: St. Louis, Sept. 11-18, 1 case.
Ohio: [illegible] 8, 1 case.
Indiana [illegible] -31, 61 cases, 2 deaths.
North [illegible] July 1-31, 50 cases.

SMALLPOX—FOREIGN

Brazil: Bahia, Aug. 6-27, 18 cases, 9 deaths; Rio de Janeiro, Aug. 15-22, 3 cases.
India: Bombay, Aug. 10-17, 2 deaths; Rangoon, Aug. 7-14, 1 death.
Italy, general, Aug. 8-Sept. 5, 18 cases; Naples, Aug. 29-Sept. 5, 9 cases, 5 deaths.
Java: Batavia, Aug. 7-14, 2 cases.
Mexico: Guadalajara, Sept. 3-9, 1 death; Mexico City, Aug. 14-28, 7 deaths.
Portugal: Lisbon, Aug. 28-Sept. 4, 12 cases.
Russia: Moscow, Aug. 21-28, 5 cases, 4 deaths; Odessa, 11 cases; Riga, Aug. 28-Sept. 4, 6 cases.
Spain: Valencia, Aug. 21-28, 1 case; Vigo, Aug. 28-Sept. 4, 1 death.
Tripoli: Tripoli, Aug. 7-28, 26 cases, 5 deaths.

YELLOW FEVER—FOREIGN

Brazil: Bahia, Aug. 6-27, 3 cases, 2 deaths.
Mexico: Merida, Sept. 9-16, 1 case; Veracruz, Sept. 24, 1 case, 1 death, from steamship Mexican.

CHOLERA—FOREIGN

China: Amoy, Aug. 7-14, 12 deaths; Chefoo, Aug. 28, 5 deaths, among Europeans.
India: Bombay, Aug. 10-17, 43 deaths; Rangoon, Aug. 7-14, 2 deaths.
Japan: Amagasaki, Aug. 14-21, 4 cases.
Netherlands: Rotterdam, Sept. 4-11, 1 death.
Russia, general, Aug. 28-Sept. 3, 520 cases, 229 deaths; Moscow, Aug. 21-28, 1 case; Riga, Aug. 28-Sept. 4, 46 cases, 19 deaths; St. Petersburg, 171 cases, 82 deaths.
Sumatra: Djambi, July 15-31, 170 cases, 78 deaths.

PLAGUE—UNITED STATES

California: Alameda County, Sept. 24, 1 case.

PLAGUE—FOREIGN

Brazil: Bahia, Aug. 6-27, 8 cases, 4 deaths.
China: Amoy, Aug. 7-14, 52 deaths; Canton, July 24-Aug. 7, 15 cases, 12 [illegible] ily 31-Aug. 7, 3 cases, 3 deaths.
Ecuador: [illegible] 4 deaths.
Egypt, general, [illegible] 3, 17 cases, 6 deaths; Alexandria, Aug. 21, 1 case, 1 death; Port Said, Aug. 20-24, 1 case, 2 deaths.
India, general, Aug. 7-14, 1,659 cases, 1,251 deaths; Bombay, Aug. 10-17, 35 deaths; Rangoon, Aug. 7-14, 27 deaths.
Japan: Kobe, Aug. 14-21, 1 case, 1 death.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, Little Rock, November 9. Sec., Dr. F. T. Murphy, Brinkley.
CONNECTICUT: Homeopathic, New Haven, November 9. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.
CONNECTICUT: Regular, City Hall, New Haven, November 9-10. Sec., Dr. Charles A. Tuttle, 196 York St.
FLORIDA: Jacksonville, November 10-11. Sec., Dr. J. D. Fernandez.
GEORGIA: Regular, Capitol Bldg., Atlanta, October 12. Sec., Dr. E. R. Anthony, Griffin.
ILLINOIS: Coliseum Annex, Chicago, October 20-22. Sec., Dr. J. A. Egan, Springfield.
KANSAS: Topeka, October 12. Sec., Dr. F. P. Hatfield, Olathe.
LOUISIANA: Homeopathic, New Orleans, November 1. Sec., Dr. Gayle Aiken, 1102 St. Charles Ave.
MAINE: Portland, November 9-10. Sec., Dr. Frank W. Searle, 806 Congress St.
MICHIGAN: Lansing, October 12-14. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.
MISSISSIPPI: Jackson, October 12. Sec., Dr. S. H. McLean.
NEW JERSEY: State House, Trenton, October 19-20. Sec., Dr. E. L. B. Godfrey, Camden.
NEW MEXICO: Santa Fe, October 11-12. Sec., Dr. J. A. Massie.
NEVADA: Carson City, November 1. Sec., Dr. S. L. Lee.
OKLAHOMA: Ione Hotel, Guthrie, October 13. Sec., Dr. Frank P. Davis, Enid.
TEXAS: Levy Bldg., Greenville, November 9-11. Sec., Dr. M. E. Daniel, Honey Grove.
WEST VIRGINIA: Chancellor Hotel, Parkersburg, November 9-11. Sec., Dr. H. A. Barbee, Point Pleasant.
WYOMING: Laramie, October 20-22. Sec., Dr. S. B. Miller.

Higher Entrance Requirements in Boston

Boston University School of Medicine announces that in 1912, besides a four-year high school education, one year of attendance, or its equivalent, at a college or technical school will be required for admission, this year's work to include English, Latin, German or French, mathematics, physics, chemistry and biology.

With twenty-five medical colleges already enforcing this standard and twenty-five others which have pledged themselves to do so, the adoption of thorough courses in these preliminary sciences in the requirements for admission to all our medical colleges in the next few years is practically assured.

Ohio Reciprocity Report

Dr. George H. Matson, secretary of the Ohio State Medical Board, sends us a report of reciprocal licenses issued by that board since Jan. 1, 1909. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1906)	Dist. Colum.
Hahnemann Medical Coll. and Hosp. Chicago	(2, 1908)	Illinois
American Medical Missionary College	(1907)	Illinois
Rush Medical College (1903)	(1906)	Illinois
Northwestern University Med. School (1907)	(1908)	Illinois

Bennett Medical College	(1908)	Iowa
Indiana	(1908)	Indiana
Indiana	(1907)	Indiana
Johns H	New York; (1906)	Maryland
Baltimor	(1902)	New York
Louisvill	(1890)	Illinois
College c Baltimore	(1900)	W. Virginia
Universi Med.	(1907) (1908)	Michigan
St. Louis University	(1908)	Illinois
University of Buffalo	(1901)	New York
Starling Medical College	(1893)	W. Virginia
Columbus Medical College	(1887)	W. Virginia
Medical College of Ohio	(1897)	Indiana
Eclectic Medical Institute, Cincinnati	(1891)	Indiana
University of Naples, Italy	(1900)	New York

Ohio June Report

Dr. George H. Matson, secretary of the Ohio State Medical Board, reports the written examination held at Columbus, June 8-10, 1909. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. Aside from the written examination, practical laboratory tests were required. The total number of candidates examined was 183, of whom 170 passed and 13 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Denver and Gross College of Medicine	(1906)	80.8
College of Physicians and Surgeons, Chicago	(1906)	76.8
Rush Medical College	(1909)	87.3

Marriages

HARVEY LEONARD, M.D., to Miss Neva Bell Drase, at Easton, Md., September 22.

J. KNOX INSLEY, M.D., Tangier, Va., to Miss Helen Horn, at Baltimore, September 18.

GEORGE HENRY SCHROEDER, M.D., to Miss Elsa Niemeyer, both of Chicago, September 18.

WALTER S. CHERRY, M.D., to Miss Frances Phillips, both of Table Rock, Neb., September 21.

PENDLETON GARDNER, M.D., Haileyville, Okla., to Miss Ida A. Flickinger of Arcola, Ill., September 16.

SAMUEL LUTHER BARE, M.D., to Miss Nellie Ruth Schaeffer, both of Westminister, Md., September 22.

WILLIAM H. COOGAN, M.D., Bryn Mawr, Pa., to Miss Alice L. Prince of Vineland, N. J., September 18.

ALEXANDER M. MACAULAY, M.D., Belt, Mont., to Miss Anna M. Eitelgoerge of Rome, Ind., September 7.

ELIAS BURTON HOWELL, M.D., Tiffin, Iowa, to Miss Bertha Hemsworth of Cedar Falls, Iowa, September 23.

JOHN JACOB REMSBERG, M.D., Walkersville, Md., to Miss Harriet English Everett, at Hamilton, Va., September 22.

Deaths

George Cuvier Harlan, M.D. University of Pennsylvania, Philadelphia, 1858; of Philadelphia; a member of the American Medical Association; of Philadelphia; surgeon in the Navy and later surgeon of the Eighth Pennsylvania Volunteer Cavalry in the Civil War; a member and once president of the American Ophthalmological Society and Philadelphia College of Physicians; consulting surgeon to Will's Eye Hospital; ophthalmologist to the Pennsylvania Hospital and Pennsylvania Institute for the Blind and Pennsylvania Institute for the Deaf and Dumb; emeritus professor of diseases of the eye in the Philadelphia Policlinic; chief of the ophthalmologic section at the Louisiana Purchase Exposition, St. Louis; died in Chestnut Hill Hospital, after being thrown from a horse, September 22, sustaining a fracture of the spine, aged 74.

Xenophon Christmas Scott, M.D. Western Reserve University, Cleveland, 1867; College of Physicians and Surgeons, New York City, 1869; a veteran of the Civil War; for many years a member of the American Medical Association; formerly president of the Mississippi Valley Medical Association; ophthalmic and aural surgeon to the German Hospital, Cleveland; and professor of ophthalmology, otology and laryngology in the Western Reserve University; founder and surgeon-in-chief of the Cleveland Eye, Ear and Throat Institute; in charge of a military hospital in Heidelberg during the Franco-German war; a well-known specialist on diseases of the eye; died at his home in Cleveland, September 30, from cerebral hemorrhage, aged 66.

John Janvier Black, M.D. University of Pennsylvania, Philadelphia, 1862; a member of the American Medical Association; College of Physicians, Philadelphia, and National Association for the Study and Prevention of Tuberculosis; acting assistant surgeon U. S. Army, from 1862 to 1864; president of the board of trustees of the Delaware State Hospital, Farnhurst; and a trustee of Delaware College, Newark; authority on the culture of fruit trees and author of "Forty Years in the Medical Profession;" died at his home in New Castle, Del., September 27, from uremia, aged 71.

William H. Felton, M.D. Medical College of Georgia, Augusta, 1844; four years later ordained a clergyman of the Methodist Episcopal Church South; a volunteer surgeon in the Confederate service during the Civil War; a member of the forty-fourth, forty-fifth and forty-sixth congresses from the seventh district of Georgia; and for four terms a representative in the state legislature; died at his home in Cartersville, September 24, from acute gastritis, aged 86.

Leonard Warring Arnold, M.D. Medical College of Ohio, Cincinnati, 1877; Vanderbilt University, Nashville, Tenn., 1882; health officer of Florence, Ala.; a member of the board of censors of Lauderdale county; formerly president of the local board of U. S. pension examining surgeons; local surgeon of the Louisville and Nashville Railroad; died in Memphis, Tenn., September 25, from cerebral hemorrhage.

Edwin Rutherford Willard, M.D. Rush Medical College, Chicago, 1852; of Joliet, Ill.; a member of the American Medical Association; consulting surgeon to St. Joseph's and Silver Cross hospitals, Joliet; surgeon of the Thirteenth Illinois Volunteer Cavalry during the Civil War; died at his old home in Wilmington, Ill., June 22, from nephritis, aged 79.

Francis Marion Slemons, M.D. University of Maryland, Baltimore, 1860; a member of the Medical and Chirurgical Faculty of Maryland; and for forty-nine years a practitioner of Salisbury; clerk of the Circuit Court of Wicomico county from 1885 to 1891; died at the home of his son in Baltimore, September 22, from cerebral hemorrhage, aged 70.

Edward N. Shaw, M.D. Atlanta (Ga.) Medical College, 1884; a member of the Milam County (Texas) Medical Society; major and surgeon Fourth Texas Infantry, U. S. V., during the Spanish-American War; major and surgeon Texas National Guard; owner and superintendent of the Milam Hospital; died in that institution, August 31, aged 48.

James G. Hart, M.D. Eclectic Medical Institute, Cincinnati, 1873; a member of the Kentucky State Medical Society, and twice president of the Western Kentucky Medical Society; supreme medical director of the National Fraternal Union; died suddenly at his home in Murray, September 23, from heart disease, aged 60.

Edgar I. Bradley, M.D. College of Physicians and Surgeons, Chicago, 1894; a member of the American Medical Association; formerly secretary of the Madison County (Mont.) Medical Society, and owner of the Virginia City Hospital; died at his home in White Sulphur Springs, Mont., September 21, aged 38.

William Hart Withrow, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1883; formerly of Spring Station, Ky.; for four and a half years assistant superintendent of the Minnesota State Hospital, Rochester; died at the home of his sister in Minneapolis, September 12, from paresis, aged 52.

Henry F. Battey, M.D. Cleveland University of Medicine and Surgery, 1884; formerly of Boulder, Colo.; died in McAllen, Texas, February 17, from the effects of a gunshot wound, self-inflicted, it is believed with suicidal intent, while despondent on account of ill health, aged 46.

James D. Guy, M.D. Geneva (N. Y.) Medical College, 1868; a member of the Medical Society of the State of New York; health officer of the township of Chenango; and coroner of the northern district of Broome county; died at his home in Chenango Forks, September 15, aged 68.

Simeon Palmer Lloyd, M.D. University of Pennsylvania, Philadelphia, 1893; city physician of Savannah, colored department, from 1895 to 1900; a member of the medical staff and treasurer of the Charity Hospital for the Colored; died at his home in that city, September 25.

John B. White, M.D. University of Tennessee, Nashville, 1882; of Fall Branch, Tenn.; for fifty-two years a practitioner; at one time a representative from Washington county in the legislature; died at the home of his daughter in Baileyton, Tenn., September 9, aged 78.

Orrin Hayden Evans, M.D. Starling Medical College, Columbus, Ohio, 1898; formerly city physician of Springfield, Ohio; a member of the Clark County Medical Society; died at the home of his mother in Jackson, Ohio, September 20, from pulmonary tuberculosis, aged 35.

John Willis Mitchell, M.D. Jefferson Medical College, Philadelphia, 1889; of Clarksville, Ark.; physician of Johnson county; a member of the Arkansas Medical Society; was shot and killed by his business partner at Clarksville, September 11, aged 42.

Ernest Edward Barker, M.D. State University of Iowa, Iowa City, 1907; a member of the North Dakota Sixth District Medical Society and health officer of Underwood; died suddenly at his home, September 9, from cerebral hemorrhage, aged 28.

George H. Berry, M.D. Washington University, Baltimore, 1848; Georgetown University, Washington, D. C., 1850; a member of the Somerset County (Md.) Medical Society; died at his home in Hopewell, September 10, from rheumatism, aged 84.

Albert Michael Fischer, M.D. College of Physicians and Surgeons, Chicago, 1906; of Kaukauna, Wis.; a member of the American Medical Association; died in St. Mary's Hospital, Oshkosh, Wis., September 21, from anterior poliomyelitis, aged 27.

Walter H. Vinal, M.D. College of Physicians and Surgeons, Baltimore, 1897; a surgeon of volunteers during the Spanish-American War with service in Cuba; died at his home in Hamilton, near Baltimore, September 27, from pneumonia, aged 35.

Gardner C. Wood, M.D. New York University, 1846; representative from Somers, Conn., in the general assembly in 1862; for more than half a century a fruit culturist and scientist; died at his home in Somers, March 7, aged 85.

Alfred M. Webster, M.D. Chicago Homeopathic Medical College, 1887; general secretary of the New Era Association of Grand Rapids, Mich.; shot and killed himself in the office of the organization, September 30, aged 60.

Fenton G. Helms, M.D. Cincinnati College of Medicine and Surgery, 1873; a member of the Ohio State Medical Association; formerly a member of the city council of Uhrichsville; died at his home, September 24, aged 59.

Clifford Llewellyn Pike, M.D. Medical School of Maine, Brunswick, 1881; formerly secretary of the Oxford County (Maine) Medical Society; died at his home in Saco, Maine, September 20, from pneumonia, aged 50.

John James Babington, M.D. Long Island College Hospital, Brooklyn, 1894; a member of the Medical Society of the State of New York; died suddenly at his home in Brooklyn, September 27, from angina pectoris, aged 51.

James L. Penney, M.D. Western Reserve University, Cleveland, 1873; for half a century a physician of McKeesport, Pa.; assistant surgeon of volunteers during the Civil War; died at his home, September 21, aged 71.

William Caldwell, M.D. University of Dublin, Ireland, 1848; for two years editor of the Blairsville (Pa.) *Appalachian;* died at the home of his daughter in Johnstown, Pa., September 13, from senile debility, aged 81.

Marshall Alexander Gilreath, M.D. University of Nashville and Vanderbilt University, Nashville, Tenn., 1891; of Selma, Cal.; *died in the Selma Sanitarium, September 22, from intestinal obstruction,* aged 46.

Earl Carlton Smith, M.D. Eclectic College of Physicians and Surgeons, Indianapolis, 1893; of Indianapolis; died suddenly at the home of his sister in that city, September 19, from heart disease, aged 37.

Henry R. Case, M.D. George Washington University, Washington, 1873; a member of the American Medical Association; died at his home in Flint, Mich., Dec. 5, 1908, from cancer of the neck, aged 60.

Enoch Mills Baker, M.D. New York University, New York City, 1890; a member of the American Medical Association; died suddenly at his home in Jersey City, N. J., from spinal disease, aged 48.

Martin H. Calkins, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1868; a member of the Iowa legislature from 1882 to 1884; died at his home in Wyoming, September 28, aged 81.

Joseph Carson Beckham, M.D., one of the oldest practitioners of Zebulon, Pike county, Ga.; died at the home of his son in Atlanta, Oct. 31, 1908, from cerebral hemorrhage, aged 88.

Frederick Cobbold McCallum, M.D. University of Toronto, 1866; Bellevue Hospital Medical College, New York City, 1866; died at his home in Hersey, Mich., September 18, from jaundice.

John Alexander Harper, M.D. Memphis (Tenn.) Hospital Medical College, 1896; of Lux, Miss.; died in Hattiesburg, Miss., January 14, from carcinomma of the cecum, aged 47.

W. Gregg Austin, M.D. Memphis (Tenn.) Hospital Medical College, 1893; a member of the Mississippi State Medical Association; died at his office in Utica, September 25, aged 44.

Robert Marion West, M.D. University of Louisville (Ky.), 1860; a member of the American Medical Association; died at his home in Clarendon, Ark., September 23, aged 77.

Charles W. Harper, M.D. University of Maryland, Baltimore, 1869; died at his home in Halethorpe, near Baltimore, May 14, from senile debility, aged 71.

Alfred Ernest Pleavin, M.D. Bennett Medical College, Chicago, 1906; died at his home in Elgin, Ill., September 22, from acute meningitis, aged 29.

Emmett E. Richardson, M.D. Cleveland University of Medicine and Surgery, 1893; died at his home in Dundee, Mich., September 18, aged 50.

Robert E. Tweedy, M.D. University of Pennsylvania, Philadelphia, 1856; died at his home in Courtland, Ala., August 27, aged 78.

Milton D. M. Batdorf (license, Berks county, Pa.); of Bethel, Pa.; died March 7, from cerebral hemorrhage, aged 65.

George W. Bell (license, Mo., 1892); an eclectic practitioner of Kansas City; died at his home, June 19, aged 71.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Correction: Through a mistake, in The Journal, September 25, the wrong program appeared under the heading, "First Month—Fourth Weekly Meeting." Instead of "Diseases of Cerebral Veins and Sinuses, etc.," there should have appeared "Surgery of Pericardium and Heart, etc.," printed below.

First Month—Fourth Weekly Meeting

Surgery of Pericardium and Heart

Pericardium: Injuries; diagnosis and treatment. Hemopericardium and hydropericardium; diagnosis of each. Indications and technic of aspiration of pericardium, of pericardiotomy.

Heart: Injuries, character of wounds. Indications for surgical treatment.

SURGERY OF MEDIASTINUM

INJURIES: Rarity, structures injured.

MEDIASTINITIS, ACUTE AND CHRONIC: Etiology.—Acute, external and internal wounds, extension from adjacent viscera, cellulitis of neck, etc. Chronic, tuberculosis, caries of vertebra, etc. Symptoms. Treatment.

TUMORS OF MEDIASTINUM

Varieties. Symptoms and diagnosis.

Monthly Meeting

The Treatment of Penetrating Wounds of the Thorax.
The Symptoms and Diagnosis of Empyema.
The Present Status of the Surgery of the Heart.

REFERENCE BOOKS FOR THE FIRST MONTH

Beck: Surgical Diseases of the Chest.
Keen: Surgery.
Bryant and Buck: Practice of Surgery.
Von Bergman and Bull: System of Surgery.
Paget: Surgery of the Chest.
Ricketts: Surgery of Heart and Lungs.

Second Month—Second Weekly Meeting

DISEASES OF THE BRAIN

DISEASES OF THE MENINGES

PACHYMENINGITIS INTERNA: Etiology, age, sex, alcohol, acute infection. Pathology, changes in dura, in pia, in bloodvessels. Presence of (a) subdural vascular membrane; (b) simple subdural hemorrhage. Changes in brain structure. Diagnosis.

PIAL HEMORRHAGE: In new-born, frequency, location, causes, immediate effects, remote effects. In later life, causes, location, symptoms.

LEPTOMENINGITIS: Etiological classification.* 1. Primary, (a) cerebrospinal fever (diplococcus intracellularis, (b) pneumococcic (pneumococcus). 2. Secondary (due to bacillus tuberculosis, pneumococcus, pyogenic cocci (streptococci and staphylococci), acute infections (typhoid, influenza, diphtheria, etc.). Symptoms. History of previous infection. Invasion period. Headache, delirium, convulsions, vomiting, constipation, muscular rigidity. Basilar symptoms. Course and terminations.

CEREBRAL ANEMIA AND HYPEREMIA: Etiology, diagnosis and prognosis of each.

CEREBRAL ARTERITIS:† Etiology and pathological changes of (a) acute arteritis, (b) periarteritis, (c) chronic arteritis (atheroma), (d) arteriosclerosis, (e) syphilitic arteritis.

Society Proceedings

COMING MEETINGS

Amer. Association of Railway Surgeons, Chicago, October 20-22.
American Public Health Association, Richmond, Va., Octcber 19-22.
Hawaiian Territorial Medical Society, Honolulu, November 19.
Kentucky State Medical Association, Louisville, October 19-21.
Medical Association of the Southwest, San Antonio, Tex., Nov. 9-11.

Southern Medical Association, New Orleans, November 9-11.
Vermont State Medical Assn., White River Junction, Oct. 14-15.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Fifty-Ninth Annual Session, held in Philadelphia, Sept. 27-30, 1909

The President, DR. GEORGE W. WAGONER, Johnstown, in the Chair

Address of Welcome and Presentation of Flag

DR. FREDERICK P. HENRY, Philadelphia, delivered an address of welcome on behalf of the Philadelphia County Medical Society and presented to the society a flag designed by a committee of the county society. The flag was accepted by the president on behalf of the state society and a motion was passed by a rising vote that it be accepted as the official banner of the Medical Society of the State of Pennsylvania.

An address of welcome was also made by the Hon. John E. Reyburn, mayor of Philadelphia.

Secretary's Report

The state of the society was reported by the secretary, Dr. Cyrus L. Stevens, Athens. The sixty-three component county societies were stated to have done more scientific work and to have held better meetings during the year than in any previous year. The present membership is 5,207, a net gain of 203 during the year.

President's Address: Physicians and the Public

DR. GEORGE W. WAGONER, Johnstown: There seems to be a lack of harmony between the public and the medical profession which has caused antagonism and open warfare on matters of immense importance to all, and a disinclination on the part of the public to deal fairly with subjects which all true medical men consider necessary to the welfare of the public and the profession. If the reason for this antagonism can be discovered, some method may be devised by which the public mind may be disabused; but while pointing out the injustice of the public we should not be blind to our own shortcomings. If in ordinary active practice we are more interested in watching and noting the phenomena of disease than in securing the comfort of the patient, we are missing the true object of our science and art, which is helpfulness. If we attempt to prove theories in the application of remedies while our patients linger in uncertainty and disability, then do we fail in helpfulness. If we clash over the minute and technical measures while neglecting the fundamental means of renewing life and health, we fail to be helpful. The keynote of success is helpfulness. If it be helpfulness on scientific observation, deduction and knowledge, it marks the highest and most desirable attainment possible to an educated physician. The sick are not cured by knowledge alone. But knowledge joined with gentleness, tact, amiability and sincere sympathy is invincible. The true ideal for a medical man is to become a bringer of peace to those entrusted to his care, rather than to acquire a store of worldly goods by commercializing his work among his people. Three hindrances to this ideal are ignorance, superstition, and incompetence; ignorance on the part of the public of the basic motives which have caused unselfish physicians to assume their life-work of personal sacrifice and responsibility for the good of others; ignorance concerning the benefits of prevention rather than the cure of disease. Notwithstanding the claims to enlightenment there is a taint of absurd superstition corrupting the mental processes of multitudes of people. Incompetence among medical men is an ever-present danger to the public. The most important problem concerning the dignity and material welfare of the medical profession to-day is to convince men, women and children that we as physicians strive to be helpful and to protect them from disasters following ignorance, superstition, disease and incompetency; that we desire to advance the standard of preliminary and scientific education of all physicians so that competency may be rewarded and incompetency be rejected by the public. Let us all open our minds to truth wherever found; our hearts to its disciples under whatever name they may be known, and as the highest object of our professional lives strive only to be bringers of peace to our fellow men.

Sanitary Science and the Social Evil

REV. FLOYD W. TOMKINS, D.D.: This evil is becoming so tremendous that a man must recognize that he fulfills his duty neither to God, to man, nor to himself unless he looks into it, and studies and plans to see what can be done. I count it a privilege to say a few words as a minister who has long been interested in this subject, and to urge on you the eradication of this disease in comparison with which the spread of tuberculosis is as nothing. This is not merely a general question of purity or impurity. Let me give you an illustration which is only one of a thousand which could be given and one of which I have direct knowledge. A young man married, though infected with this disease. His health soon failed, tuberculosis developed, and he was about to die. On his death bed his wife said to him: "You have poisoned my body and ruined my life, and I pray God that in hell your mind may suffer just retribution." That is not an isolated case. We ministers know about cases that make our hearts ache and yet we are absolutely helpless in the vast majority of them. What can you and I do practically about it? Cannot we at first educate those with whom we come in contact? Cannot we put aside that modesty to which, God knows, we would like to hold to ourselves? Most of us would be glad to go back to the innocence that we had in our childhood. Why should we not urge on mothers that they teach their daughters concerning this evil, teach them not only to be pure in mind and body, but warn them of this terrible evil which is spreading through the land with such fearful results. Much can be done in this and other directions if we will only be honest enough, fearless enough, high-minded enough to recognize our responsibility.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-Second Annual Meeting, Held at Fort Wayne, Ind., Sept. 21-23, 1909

(Continued from page 1122)

Surgical Treatment of Tumors of the Bladder

Dr. John W. Keefe, Providence, R. I.: The surgery of tumors of the bladder is in a transitional state. The last word has not been said. While the perineal and vaginal routes have been abandoned by most surgeons, some now prefer the urethral, while others the suprapubic extraperitoneal, and yet others the abdominal intraperitoneal route, or a combination of both. The medical treatment of tumors of the bladder is often prolonged until surgery is of no avail. The suprapubic operation is the method most frequently employed at the present time, although the abdominal intraperitoneal route has many points in its favor. It gives one plenty of room in which to operate, and one can see exactly where to excise or cauterize the growth. The choice of the anesthetic is important for consideration in the removal of bladder tumor, as the patients are often found in a debilitated condition from loss of blood, sepsis or diseased kidneys. Nitrous oxid gas and oxygen are preferable on account of their safety and the non-irritation of the kidneys. The operation may be rapidly performed, and takes much less time than it does to describe it.

DISCUSSION

Dr. C. C. Frederick, Buffalo: I have operated on three patients for malignant disease of the bladder. In the first case, which occurred six or seven years ago, the tumor was located in the posterior wall of the bladder, in women, just back of the trigone. Following the removal of the tumor she made a good recovery, went on for two or three years, and I supposed was going to get perfectly well. But she had a recurrence to the left side of the original scar. She did not have a secondary operation, and eventually died of anemia.

Dr. Ernst Jonas, St. Louis: With the cystoscope we are able to decide the size of the tumor, but not its character.

Dr. M. I. Rosenthal, Fort Wayne: In a case of cancer of the uterus, which involved the bladder, I did a radical operation for the removal of the uterine cancer, also removing a piece of the bladder in a woman of 58. She is still in fairly good health.

Chylous Cyst of Iliac Mesentery

Dr. Charles E. Condon, Buffalo: The patient in this case was a boy, 5 years and 11 months old. The usual incision for an apppendix operation was made. On opening the abdomen a tense cystic tumor presented, which resembled an ovarian cyst, but was more elastic and had the color of omentum. On enlarging the abdominal incision, the tumor was found to be the distended iliac mesentery, beginning about eighteen inches above the ileocecal valve. It was ovoid, with a valley lodging the bowel, and dwindling toward the posterior mesenteric attachment into a wedge-shaped separation of the mesenteric layers. The ileum corresponding to the mesenteric cyst was compressed into a white cord, while above it was distended. After incising the cyst, about two quarts of milky fluid gradually drained away, there was a reduction of tension, allowing the vessels of the bowels to fill and the pallor to disappear, while the relief of pressure caused the lumen of the bowel to become patulous, and the distention above passed away. The cyst was sutured to the abdominal incision, and was drained by a rubber tube held in place by a stitch; otherwise the abdominal incision was closed with through-and-through sutures of silkworm gut. The relief was almost immediate.

DISCUSSION

Dr. Miles F. Porter, Fort Wayne, Ind.: In one case, on opening the abdomen, I found that I had a volvulus to deal with, but in unravelling the volvulus I found that it was due to chylous cysts of the mesentery. The gut was resected, but the patient died from the continued progress of the peritoneal infection.

Dr. Ernst Jonas, St. Louis: In regard to intestinal obstruction, produced by chylous cyst, I wish to emphasize the importance of not giving medicines with a view to relieving such intestinal obstruction when it is caused by these cysts. We should never try at this stage in surgery to remedy ileus by medicine, which we give to patients by mouth, as it is impossible to accomplish anything by them in any case of true obstruction.

Dr. A. H. Ferguson, Chicago: I have never encountered a chylous cyst of the mesentery in my surgical experience, and I think it is well for us in discussion of such papers to point out the relative infrequency of these cases.

The Embryo Abdominal Surgeon, with Inadequate Preparation and Knowledge

Dr. J. Henry Carstens, Detroit: In every large center, say the county seat, there ought to be a hospital and a surgeon, or surgeons, who not only have picked it up but who have been prepared for the work by a thorough course of hospital training; and it seems to me that these men should limit their practice to surgery, and not compete with their colleagues. State boards should take up this question and issue a special license to those who want to practice special lines of surgery. In conclusion I would say: 1. Abdominal surgery by embryo surgeons should be prohibited. 2. Thorough preparation in a proper hospital, as an assistant for one year, should be the minimum requirement. 3. Those who want to practice abdominal surgery should furnish evidence of qualification. 4. Nothing herein contained should prevent any general practitioner from doing abdominal surgery in an emergency.

When Shall We Operate for Ruptured Ectopic Gestation?

Dr. R. R. Huggins, Pittsburg, Pa.: It has been my custom always to delay operation for a few hours in ruptured tubal pregnancy when all signs pointed toward a temporary cessation of the hemorrhage. In the vast majority of instances the hemorrhage has ceased temporarily when the consultant is called. The length of time which has passed since the hemorrhage begun varies. The attending physician will usually say that when he first saw the patient she was in a state of collapse, but that now, that is several hours later, there is some improvement. The pulse is slightly better, the air hunger has disappeared, etc. A pulse which was hardly perceptible when he first saw the patient is now easily counted and is of better volume; reaction has already begun. The formation of a clot in the pelvis has plugged the bleeding point and the force of the blood stream is now so low that for a time, at least, there is little danger of recurring hemorrhage. Who can say, and by what means are we to determine, how long this period of apparent rescue from death by Nature's efforts may continue? Doubtless in many cases hemorrhage does not recur, but my experience convinces me that some further advance must be made in diagnostic skill before it can be said that hemorrhage, severe, and even fatal, may not recur in a given case. A series of experiments on 50 dogs showed the coagulating time of the blood to average 3 minutes 28.10 seconds. The average time in 50 normal individuals taken by the same instrument was 6 minutes 45 seconds. There is a considerable difference in the time of coagulation of the blood of the dog as compared to the human. There is undoubtedly greater protection against continued hemorrhage in the dog because of this rapid coagulability of the blood. We all know that owing to the increased blood supply to the pelvic organs during pregnancy a small wound made in the uterus or in fact in any part of the pelvis will bleed profusely. Without careful consideration of these facts, experiments on animals in the study of this subject are of no practical importance. It is irrelevant to compare hemorrhage from other parts of the body to that which occurs from the torn vessels of a congested pregnant tube.

Recent papers advocating delay in operation have served an important purpose, because they have emphasized the fact that the patient usually rallies from the primary hemorrhage and that it is unnecessary, as a rule, to operate while the patient is in extreme shock. It is undoubtedly true that in a large percentage of the cases a few hours can be well spent in allowing the patient to react so that operation will be attended by less danger. That it can be postponed indefinitely without great risk to the patient has not been true in my experience.

DISCUSSION

Dr. H. W. Longyear, Detroit: There should be no hesitation on the part of the surgeon in regard to the necessity of operating immediately in cases of recent ruptured tubal pregnancy.

Dr. Hugo O. Pantzer, Indianapolis: Standing as we do in this class of cases oftentimes in the presence of doubt, when life is menaced, we cannot decide otherwise than to chance it with the doubt in favor of an operation.

Dr. W. H. Humiston, Cleveland: To me delay is dangerous doctrine. There should be very little trouble in making a diagnosis of ruptured ectopic pregnancy. If the rupture is sufficient to cause shock one cannot tell whether the shock will be overcome or not, and I do not hesitate to operate on all these patients who come into my hands whether they are in shock or not.

Dr. Thomas B. Noble, Indianapolis: It is bad teaching to advise delay in operating in cases of ruptured ectopic pregnancy. When Dr. Robb advocated procrastination, I said that some women would die as the result of such teaching. I wish to subscribe *in toto* to the advice given by Dr. Huggins, and to affirm that these patients should be operated on immediately.

Dr. A. B. Miller, Syracuse, N. Y.: We should not procrastinate in operating in these cases of ruptured ectopic pregnancy promptly. In over a hundred patients operated on immediately I have only lost three.

Dr. John Young Brown, St. Louis: I have seen a number of cases of ectopic pregnancy, and I have not been able to reason out from this experience why gynecologists should differ as to the proper time to operate. With modern methods of combating shock, and particularly by the use of salt solution by hypodermoclysis and by the method which Andrews has accentuated in the treatment of gunshot wounds in which the hemorrhage is severe, namely, buttonholing the upper abdomen as soon as the abdomen is opened, and starting the salt solution to flow immediately on the opening of the abdomen, a large majority of these patients can be saved by prompt action.

Dr. Albert Goldspohn, Chicago: Of 80 cases of ectopic pregnancy that I have dealt with in one way or another, I have only known of 2 patients to die from this affection who were not operated on.

Dr. C. C. Frederick, Buffalo: I have operated on about 130 or 140 patients with ectopic pregnancy in my city; 5 per cent. of these have been rapidly bleeding cases, and the other 95 per cent. were cases in which rupture had taken place and there were symptoms of recurrent bleeding extending over a period of 2, 3, 4 or 5 weeks, or even 6 months. I have operated on women who have had recurrent hemorrhages five or six months after the primary rupture. I recall one case in which hemorrhage stopped, the woman did not have another rupture, and she was not operated on. All things considered, I am in favor of early operation in cases of ruptured ectopic pregnancy. I believe we should insist on stopping hemorrhage in these cases, as well as bleeding which may take place in any other part of the body, namely, by tying the bleeding vessel and stopping the hemorrhage.

Dr. M. I. Rosenthal, Fort Wayne, Ind.: It has been my practice to operate on these cases of ruptured ectopic pregnancy as soon as the diagnosis is made. In all the cases that I have diagnosed early and in which I have operated, there have been no deaths, but in those that were operated on late I got a mortality in each case.

Dr. E. Gustav Zinke, Cincinnati: It is just as wrong to say that every patient with ectopic gestation must be operated on as it is that every case of this nature does not need operation. There are patients who recover without operation. This should not be forgotten. Most gynecologists probably know of instances in which operation has been proposed with counsel and without counsel, was refused by the family, and patients have recovered, and they had the laugh on the operators. I agree with Dr. Robb, and I must protest against operating in every case of ruptured ectopic pregnancy.

Dr. J. Henry Carstens, Detroit: If a woman is suffering from internal hemorrhage, as that from a ruptured ectopic pregnancy, she ought to be operated on promptly. I believe in operating in these cases promptly.

Rupture of the Uterus

Dr. Ralph W. Lobenstine, New York: Ruptures of the uterus during labor may be divided into complete, and incomplete ruptures of the vaginal vault. Of the 78 cases in a series of 78, at the New York Lying-in Hospital, there were 46 complete ruptures, 29 incomplete, and 3 ruptures of the vaginal vault. The etiology of the complete ruptures was as follows: (1) Spontaneous ruptures were due to pelvic contraction in 21 cases; Cesarean section scar, 2 cases; scar tissue after amputation of cervix, 1 case; transverse presentations, 3 cases; and hydrocephalus, 1 case. (2) Traumatic ruptures were due to high forceps, in 3 cases; internal podalic version, 5 cases; *accouchement forcé*, 6 cases; and embryotomy, 1 case. (3) Ruptures due both to version and transverse presentation, 3 cases. It is noteworthy that the large percentage of complete ruptures occur in multiparæ, and especially in patients in whom the uterine musculature has been weakened by inflammation.

The common location for the rupture is the lower uterine zone. There are two fundamental types, the longitudinal and the transverse, but there is often more or less fusion of these types. In the list there were 26 that probably started as the vertical type, and 20 as the transverse. Of the 26 longitudinal tears 18 occurred on the left side, 6 on the right, and 2 near the mid-line. Of the 20 transverse ruptures, 13 occurred on the anterior wall and 7 on the posterior. In the presence of a dystocia, especially in the generally contracted pelvis of moderate grade, as the lower zone becomes thinner and thinner, and more and more distended, the lower portion of the cervix tends to become imprisoned between the fetal head and the pelvic brim. At the same time the contraction ring assumes a high level, and acts as the upper fixed point. The lower zone finally has to give way, if relief is not at hand. The symptoms are: (a) Premonitory; (b) the signs of shock and hemorrhage, with or without the development of sepsis. The child only escapes into the peritoneal cavity in about 15 per cent. of cases. Of the 46 patients treated in the hospital, there were three with rupture at the uterovaginal junction. Such ruptures are seen most frequently as the result of transverse presentations, and of trauma due to faulty instrumentation. The posterior vaginal vault is injured more frequently than the anterior. The spontaneous ruptures are due to a tremendous distention and stretching of either anterior or posterior vaginal vault. The pelvic contraction is usually of high grade.

Incomplete ruptures of the uterus may be either spontaneous or traumatic, and either vertical or transverse. The common traumatic causes are *accouchement forcé*, forceps, version, extraction of the after-coming head, and embryotomy. Rapid dilatation in placenta prævia centralis gave the greatest number of ruptures of this type. The spontaneous ruptures usually depend on old scar tissue in the cervix or vaginal fornices.

The maternal mortality in the list of 78 cases was 53.8 per cent.; the fetal mortality was 70 per cent.

The treatment of incomplete ruptures consists of tamponage alone or with sutures; rarely laparotomy.. Treatment of vaginal vault ruptures comprises tamponage or laparotomy, with suture of laceration, rarely hysterectomy. In complete ruptures, if the child is free in the peritoneal cavity, an abdominal section should be performed. If the child is still in the uterus, and the tear is a bad one, the woman should be delivered at once, by using tamponage or doing hysterectomy on the spot. The patient should not be moved. If the child is still in the uterus, and the tear is not a bad one, it will be best to move the patient to hospital before delivering. When the diagnosis is first made, after delivery of the child, tamponage may be relied on, if the patient is in good condition. A laparotomy is useless in the presence of severe shock.

DISCUSSION

DR. E. GUSTAV ZINKE, Cincinnati: Rupture of the uterus from purely obstetric causes should not occur in the hands of any one who knows obstetrics. I am referring now to rupture of the uterus, due to delayed labor, the result of an obstruction which is encountered in the passage of the child, and such ruptures should be wiped from the records. Knowing the doctrine of narrow pelves, as we understand it now, no man has a right to carry a patient to the verge of rupture of the uterus, as the clinical picture which brings the threatening danger is so clear that no man can possibly overlook it. The man who has taken the history of his case and studied his patient carefully will know in advance whether he has trouble to look for or not, and he will be on his guard and look for the symptoms indicative of rupture.

DR. EDWARD J. ILL, Newark, N. J.: I want to speak of rupture of the uterus, which is produced by the application of forceps high up, in a case of non-retracted cervix. Let us make a difference between the two. A dilated cervix does not mean a retracted cervix. The forceps, as a rule, should not be put on the fetus until the cervix is retracted. This is an old rule, and is little followed.

DR. R. W. LOBENSTINE, New York: I agree with Dr. Ill. The application of the forceps high up is responsible for a large amount of damage.

Calcareous Degeneration of the Fibroid Uterus

DR. WALTER B. DORSETT, St. Louis, read a paper on this subject and presented the specimen:

On opening the abdomen the tumor was found lying loosely in the pelvis and unattached. On grasping the mass I was reminded of the sensation usually imparted in the handling of uterine fibroids with a long pedicle. A supravaginal amputation was done, and the abdomen closed within a few minutes. The patient made an uninterrupted recovery and left the hospital within eighteen days, well, and relieved of her distressing symptoms. The ligation of the renal artery of the rabbit by Litten and his subsequent discovery of deposition of calcium salts in the renal tubules, probably proves that the true etiology of calcareous deposits lies in a retrograde process due to deficiency of blood supply. It can be readily seen that during the normal atrophic changes in the uterus, due to decreased determination of blood toward the uterus, degenerative changes are apt to occur.

DISCUSSION

DR. J. HENRY CARSTENS, Detroit: Thirty or more years ago a woman came to the dispensary with fibroid tumors. At that time we did not operate on these tumors so frequently as we do to-day. She was not operated on then. About five years ago she presented herself with three tumors which were jammed in the pelvis, causing obstruction of the bowels and bladder. I operated on her, removing one tumor about six inches long, and four inches in diameter. These tumors were so hard that I could not cut them open, but had to split them with a hatchet to show the calcareous deposits. No matter how long these cases are allowed to go, these tumors will either undergo calcareous degeneration or become malignant, so on general principles all fibroid tumors ought to be removed.

DR. HUGO O. PANTZER, Indianapolis, reported a case which was similar in every respect to the one related by the author of the paper.

Ovarian Pregnancy at Term

DR. WALTER C. G. KIRCHNER, St. Louis: The clinical symptoms were those associated with tubal pregnancy. At a later stage the patient had the usual symptoms attending uterine pregnancy at term. The tumor mass originated in the right ovarian region, and as pregnancy advanced the tumor was pushed toward the left side. The patient felt fetal movements about the fifth month of pregnancy. The condition was complicated by prolapse of the uterus with pronounced edema of the cervix. The patient consented to operation, and in doing a laparotomy a cyst-like tumor was delivered through the abdominal opening. The mass resembled an ovarian cyst, and contained the fetus. This was found to be full term and well developed. It was easily resuscitated and is in good health. The tumor mass was complicated by omental and intestinal adhesions. The appendix was adherent and appendectomy performed. The left tube was free. The right tube was incorporated with the outer surface of the gestation sac. The ovarian ligament was connected with the gestation sac. The sac originated in the right ovarian region, where a broad pedicle had formed which was ligated and severed. In this region also the main blood supply was obtained. The gestation sac contained the placenta and fetal membranes. The placenta was not associated with either tube and was free in the abdominal cavity. It occupied a central and anterior position in the gestation sac. The diagnosis of ovarian pregnancy was based on the presence of the utero-ovarian ligament, the normal condition of both tubes, the location of the tumor, and the microscopic evidence of the examination of the gestation sac. Mother and child are living and in good health.

DISCUSSION

DR. E. GUSTAV ZINKE, Cincinnati: Ovarian pregnancy is a very rare thing, and I am glad we have brought before us a case which leaves no doubt in our mind as to its real character. It is remarkable what Nature will not do under these circumstances when the ovum is implanted ectopically. The most frequent cases of ectopic gestation which go to full term are those in which the tube holds out to the last. It is comparatively rare, it is true, but these are the cases in which there are no adhesions between the abdominal viscera and the ectopic gestation sac. The next in frequency is the ovarian, but here very often rupture takes place because of the brittle character of the ovarian tissue. There is another variety of ectopic gestation which goes to term, but which is the rarest of them all, and that is, in cases of tubal rupture, or in tubo-ovarian pregnancy rutpure takes place sufficiently to permit the amniotic sac, with the decidua reflexa, which is formed under these circumstances to escape into the abdominal cavity. Here the placenta continues to grow within the tube or ovary, as the case may be. Sometimes it makes its way outside of the structures and implants itself on the pelvic wall. Occasionally it happens that the membranes are broken because of the movements of the fetus, and then the fetus is found free in the abdominal cavity.

DR. ERNST JONAS, St. Louis: I recall a patient operated on by Dr. Tuholske when I was assisting him, in whom in the second month of pregnancy the entire ovum was swept away from its seat of implantation in the right tube, into the free abdominal cavity, implanted itself in the region of the liver, changed the liver tissue, the peritoneum covering the kidney, and parietal peritoneum to such a degree that it was able to change these tissues to true decidual tissue. The pregnancy went on to term and the child was removed at the end of pregnancy alive. The mother died twelve hours after the operation. We did not know at the time why she died. The specimen which we have in our possession shows that it would have been impossible to have removed the placenta by force from these organs.

DR. A. B. MILLER, Syracuse, N. Y.: In the pathologic museum of the college in Syracuse a specimen has been recently placed of an ovary which contains an ovum perhaps of two months' development. The patient was operated on by a neighboring surgeon, he supposing he was simply dealing with an ovarian cyst. The patient had been complaining of more or less pain, and on examination a small globular mass was found in the pelvis. Without taking the history of the patient as to the possibility of this being a pregnancy, the woman was operated on, the ovary removed, and found to contain this small embryo.

(To be continued)

MICHIGAN STATE MEDICAL SOCIETY

Forty-fourth Annual Meeting, held at Kalamazoo, Sept. 15-16, 1909

(Concluded from page 1123)

The Physician and the Antituberculosis Campaign

Dr. A. S. Warthin, Ann Arbor: This paper treats of the changing attitude of laymen toward medicine, of the popular demand for preventive medicine, and of the increased knowledge of the laymen concerning matters once supposed to be the property of the physician. As a result of this change, the profession of medicine is also undergoing an evolution from a science and an art professing to cure, to a science of prevention of disease. The physician of the present day must meet this changed attitude. His duties become no longer those relating to his immediate patients; but he must concern himself with the broader questions of public health and the fight against preventable diseases. In modern health board work, in school inspection, in antituberculosis work, in the fight against venereal diseases, the physician finds a legitimate field for activity. The increasing medical knowledge among the people at large demands that the physician lead these movements in the prevention and extermination of diseases. There is a growing tendency for people to consult physicians as to the state of their health and what things should be avoided or prevented. The physician must meet this new conception of medical practice or fall behind. In the fight against tuberculosis he must especially take a leading and important part.

Diagnostic Value of the Hemolytic Tests in Cancer and Tuberculosis

Dr. Frank Smithies, Ann Arbor: This work comprises observations on 158 individuals affected with various ailments, and clinically well. Apart from the cancer cases, particular interest is attached to the findings in the cases of tuberculosis, syphilis, the anemias and the diseases associated with anemia. In the clinical diagnosis, of 31 cases of malignant disease, there were 14 positive, 10 negative, 4 reverse and 3 undetermined. Of 3 cases of benign tumor, the results are, 0 positive, 3 negative, 0 reverse, 0 undetermined. Of 45 cases of tuberculosis, there were 2 positive, 27 negative, 5 reverse and 11 undetermined. Of 19 cases of syphilis, there were 4 positive, 11 negative, 0 reverse and 4 undetermined. Of other diseases, there were 36 cases, 5 positive, 20 negative, 2 reverse and 9 undetermined. Of normals, there were 24 cases, 1 positive, 23 negative, 0 reverse, and 0 undetermined. While the main mass of data is at present for any single class of disease, yet the large number of cancer cases showing this reaction should urge us to seek modifications of the method in the hope that study of various sera along other lines will lead to the firm establishment of a specific reaction for cancer and other diseased conditions which seem to have specific pathology.

DISCUSSION

Dr. Victor C. Vaughan, Ann Arbor: This work on hemolysis and the use of hemolytic tests stands on a very uncertain foundation. Work has been done recently in Wassermann's own laboratory which seems to show conclusively that the hemolytic test is due to the presence of a ferment, and all this talk about amboceptors, complements, etc., is dependent on the acidity or alkalinity of the reaction. He is somewhat uncertain about the outcome. We know a great many more things about cancer than we knew years ago, and the medical profession is making some progress, and I think we may reasonably hope that the time will come when cancer will be cured not by any serum, or by any injection, or anything of that kind, but when we may reasonably expect that after operable cancer has been removed by the knife, a return of it may be prevented.

Dr. Hugo A. Freund, Detroit: The subject of hemolysis interested me a number of years ago in the direction of the presence of hemolysis in pernicious anemia. At that time I determined the hemolysins in the urine of individuals with that disease. One of the first things was their persistence; at times they appeared one day and were absent the next. In going over the work one fact struck me, and that was there is no uniform method of estimating the hemolysins. The method suggested by Crile is open to many criticisms. The one of Richard Weil, which appeared later, is as good a test as can be used. The results not only vary in accordance with the tests used, but the personal factor has much to do with the study. I am surprised at Dr. Smithies' results in tuberculosis cases, as other reports are contrary to his findings, especially the recent reports of Ottenberg of New York, who finds a degree of hemolysis in cases of advanced tuberculosis. There seems to be some relationship between agglutinins and hemolysins.

Dr. F. Smithies, Ann Arbor: My method in general was that of Weil. I have tried the Eppstein method, and the method suggested by Crile frequently as controls. Weil's method seems more reliable. With regard to the relation of hemolysins to agglutinins, practically I know little about the subject other than what I have read and work which I have done. Perhaps my list of reverse hemolysis was rather small because I had very few late cases of tuberculosis. In the moderately advanced cases, the degree of reverse hemolysis was more marked than in the localized infections. These cases were associated with anemia, fever and cachexia.

Landmarks in the Diagnosis of Incipient Tuberculosis

Dr. Elmer F. Otis, Battle Creek: The signs and symptoms that are not positively diagnostic are the family history, the cough, expectoration, night sweats, the diaphragmatic excursions and the so-called phthisical chest. The uncertain factors that are perhaps given undue importance are dull areas on percussion, cavernous resonance, hectic flushings, one or two negative sputum examinations, *x*-ray examinations, history of excesses in vital and procreative functions or the various vices. The findings that must determine the real diagnosis are the demonstration of tubercle bacilli in the feces and sputum and a possible early hemorrhage. Spasmodic fluctuations in vasomotor phenomena or bodily temperature. History of failing health, with loss of weight and appetite; a rapid and irritable heart even when the patient is at rest. Anemia without leucocytosis, but a strong tendency to blood dyscrasia, such as hemorrhages, nose-bleed, disorders of menstruation and vasomotor disturbances. The eye and percutaneous tuberculin tests are of real, but debatable merit. Last, but not least, are auscultatory findings.

Dr. T. M. Koon, Grand Rapids: The public is beginning to learn the importance of early diagnosis of tuberculosis. Physicians throughout the State of Michigan can render a great service along the lines of prevention of tuberculosis by diagnosing these cases earlier. Every man who is doing more or less special work along this line has occasion to see patients who are in the advanced stages of tuberculosis and who have been cared for by physicians for months without knowing they had this disease. Therefore, it is highly important that the profession should appreciate the fact that the public is going to call on them to make these early diagnoses. I would urge the importance of taking a careful history in all cases. During the last few years the profession has got away from the idea that heredity plays any part in tuberculosis, and the public has become educated to a certain extent along that line, but a great many of the leaders of the profession are getting back to the idea from personal observation that the children of tuberculous parents inherit a predisposition to that disease, and they are more likely sometimes during their lives to contract tuberculosis than the children of parents who are not tuberculous. I have diagnosed early a number of cases of tuberculosis with the skin test. It is easy to apply and is harmless. This test is being used by the leading men all over the world, and its findings are valuable, so that in all cases in which our suspicions are aroused, and in which we do not find the tubercle bacilli in the sputum, we should resort to the tuberculin test before dismissing the patient.

Dr. Victor C. Vaughan, Jr., Ann Arbor: The taking of the family history is very important. In fact, in the diagnosis of incipient tuberculosis everything is important, and we must use every means in our power which will furnish any knowledge or information. The diagnosis of early tuberculosis is very important. Not infrequently other individuals in families in which there may be cases of tuberculosis come to us before they have any symptoms apparently of the disease. They may take cold easily, or they may feel a little run down, may have lost a little weight, or look a little pale. They have no cough, and they come to us to know whether they are in good health or not. In these cases a physical examination is practically negative, that is, it is very hard to detect any signs or symptoms. I believe the diagnosis of incipient tuberculosis can hardly ever be made unless the patient is watched carefully for a certain interval of time. More stress should be laid on slight rises in temperature, and on accelerated pulse. It is difficult to get these slight rises in temperature and of increased pulse, and for that reason it would be a good thing if these patients could go to hospitals, say for a period of three or four days for purposes of observation, and at the end of that time a positive diagnosis could probably be made. One of the most useful adjuncts is the use of tuberculin in the diagnosis of early cases. This may be administered subcutaneously, percutaneously, or in the eye. I prefer the ocular reaction. I cannot agree with Dr. Koon as to the reliability of the skin reaction; I have obtained it in control cases, and one may say the subjects are tuberculous, but they show no evidences of it. It is much easier to prove a patient to be tuberculous rather than non-tuberculous. In no case in which I have obtained a definite ocular reaction have I failed on observation to find undoubted evidences of tuberculosis in 250 cases. Of course, there are certain cases in which the eye reaction does not work, or no reaction is obtained.

Dr. B. R. Shurly, Detroit: The medical profession has great responsibility in the early detection of these cases. These patients are always with us. They are so numerous that it is almost astonishing to any one, who is working on this problem, to see how frequently we can demonstrate active signs of tuberculosis. There are certain definite lines of procedure in regard to the early diagnosis that I have found very helpful in elucidating some obscure or unusual lesions. It is important in examining the chest to have the clothing removed. Many practitioners in examinations of the chest do so through a little opening, and no endeavor whatever is made to reach the back which in my opinion is the all-important part in the diagnosis of this disease. I much prefer to have the percussion and auscultatory signs from the back than from the front of the chest. We know definitely where the lesions are more frequent, and these particular areas should be given more careful investigation. A routine examination should be made of the sputum. The newer tests are useful in detecting the early cases of the disease. The skin reaction in my opinion is of no value except in very early infancy, but the eye reaction is of considerable value in many doubtful cases. Observations should be carefully directed to the temperature. Examination of the throat and larynx offers considerable additional information as to the location of any possible lesions explaining early invasion in those regions.

Dr. J. Collins Johnston, Grand Rapids: We get our information from auscultation in these early cases; but we cannot make a diagnosis as a rule, with one examination. It is necessary to have these patients come to us from time to time, furnish them with thermometers, and have them take their temperatures every two hours for two or three days. I teach them to do this, and then we can get information about rises in temperature. The skin test is of inestimable value in a negative way.

Dr. Frank Smithies, Ann Arbor: If the eye reaction and skin reaction show the presence of a previously active tuberculosis, it does not necessarily mean consumption. There may be a tuberculous focus somewhere, and it is the physician's duty to find out where that focus is, and the only way to do so is by a thorough and careful physical examination. The tuberculin method of Koch is of more value in localizing infection and telling a patient he has consumption than any special reactions that may be mentioned.

Dr. Donald, Detroit: Has Dr. Shurly seen any unpleasant sequelæ from the ocular reaction?

Dr. Shurly: I have never seen any marked reaction in the way of a purulent discharge from the eye.

Urinary Infections; Treatment by Inoculations

Dr. W. T. Dodge, Big Rapids: Vaccine therapy has not been used extensively by many general practitioners because of the supposed necessity of regulating dosage by the opsonic index. In most cases the symptoms of the patient are a safe guide to the administration, and when the index is taken and does not correspond with the symptoms, it is safer to be guided by the symptoms. In sixty cases, nearly all of urinary infection, all the patients were treated with vaccines without index. Many cases were of several years' duration, in which the urine contained large quantities of pus, and which had resisted all local and general treatment. There were of *Bacillus coli communis* infection, 41 cases; mixed *B. coli communis* and *B. pyocyaneus*, 4 cases; mixed *B. coli* and streptococci, 1 case; mixed *B. coli* and micrococci, 3 cases; *B. pyocyaneus*, 8 cases; streptococci, 1 case; *Staphylococcus pyogenes aureus*, 2 cases; *Staphylococcus pyogenes albus*, 1 case.

The work was all done at the laboratory of Mercy Hospital, but the patients were under the charge of several different physicians, and the period extended from February to September, 1909. Twenty-three patients have been cured; 37 are still under treatment, the germs still existing in urine, but in every patient under treatment more than thirty days' symptomatic cure has taken place. A few of the patients had no pus in the urine, but had indication of infection at other places in the body. Many cultures of the urine have been made in cases of known infection in which the urine was normal chemically and microscopically, and in every instance the germs causing the infection have been obtained from the urine. This I consider a valuable diagnostic point in infectious diseases and one that should be followed up by other observers. Two cases of acute infection were treated, one of the colon bacillus, the other of the streptococcus, with highly satisfactory results.

Mind Cures in General and the Emmanuel Movement in Particular

Dr. Archibald Church, Chicago: Mind healing or psychotherapy is older than the story of the Garden of Eden; it is contemporaneous with the Garden itself. In olden times, the priest and physician were one and the same. Whether it was the priest of Apollo or the followers of Æsculapius, or as the medicine man in Dakota, medicine and religion went hand in hand. The influence of the mind as affecting the human body for better or worse has been known ever since men have congregated, and the influences which have dominated one and another sort of mind cure have been identical since the beginning of the world, and these influences have been exercised along rather definite plans to the attainment of a single end. That is to say, in all schemes of mind cure, whether it be scientific psychotherapy, hypnotism or the iterative vagaries of Christian science, they have all been exercised in two ways: the one establishing expectancy of improvement by the incubative method, the other by asserting better, helpful, hopeful and healthful things by the method of iteration or continued suggestion. This process of expectancy, waiting for something and earnestly anticipating benefit, is commonly described as the incubative, like the hen sitting on the egg, lives in hopes, and the sick individual always hopes and continues to hope. It is the keynote of all forms of mind healing, of all forms of psychotherapy—hope, eternal hope. The other plan is to have those who feel sure of their ground, or who are convinced that certain plans are beneficial, to insist constantly on these facts. By this iteration, the groove of health is established. In this suggestive purpose you will see that it is the element of hopeful expectancy which is the key to the situation, and it dominates the music and paints the scene and tempers the entire atmosphere. New England has given us

Christian science, which has largely for its purpose the alleviation and cure of disease. It has cured disease and will continue to cure disease so long as people adopt a hopeful expectancy toward that end. This is not saying that Christian science cures organic disease. Christian scientists do not admit that they can cure cancer or broken bones or that inflammatory processes or infections are modified by this hopeful expectancy to any considerable extent. Undoubtedly, many vagaries of feeling and worries of the flesh are benefited by Christian science.

Those of us who live in Chicago have seen the rise and fall of what has been called Dowieism. Any conception which you may entertain of Dowie as a faker or a grafter, or a mere money-getter, is absolutely besides the mark. Dowie believed he was the inspired agent of the Almighty. He believed that to him were vouchsafed messages from the archangels. He was deluded. He was convinced that what he did was under divine direction, and that those who opposed him were animated by the devil. He was sincere. Had he not been sincere the movement which he fostered and built up would have fallen away promptly, but it was his own conviction, his own righteousness and power, that enabled him to gather about him such men as made up the leaders of his church. When in the latter stages of mental disease he became absolutely irrational and thought he saw the King of England coming in a ship bringing him an immense fortune, then his followers were willing to see his insanity. Every year of his life had been the natural result of a deluded mind.

Of two physicians of equal intellectual attainments, the man of buoyant character and helpful disposition and encouraging nature, is the better physician, and his results will be better and his opportunities for doing good will be greater because he inspires this mind cure unconsciously, he inspires this hopeful anticipation of improvement. The physician should understand the forces with which he works and the obstacles he meets and the means at his disposal to get the best results by the application of mind treatment in his daily routine. Pleasant thoughts mean good circulation and good circulation means better nutrition.

The Emmanuel movement had its inception in a party of social-service workers. Dr. Worcester had his attention called to the fact that many people did not know about consumption and could not only not benefit themselves, but did not know how to check the spread of the disease. The social workers were organized to get the people out of doors. They induced consumptives to sleep in tents or on porches or in back yards. It was a fine thing, but it was not appreciated. Dr. Worcester saw the Christian science churches building and increasing all over the land, and he may have taken a tip from that cult. The other regular Protestant denominations were decreasing in attendance. But Dr. Worcester saw the defects of Chistian science. People worry. They have a lack of self-control. They are addicted to vice. These people he got together in small classes and their self-control was stimulated by pointing out the need for it. There was a moral element in it. The neurasthenics were added later. These people had fears of insanity or fears of general nervous breakdown. He insisted that they be examined by a regular physician to make sure that there were no organic defects, and that the cases were such as he might reasonably hope to benefit. The church is in a transitional stage. I do not know how, or why, or whither the trend, but these are the facts, and these people who are now seeking help in the Emmanuel movement in a few years will have tired of it and the church will have lost in grace in the meanwhile, and it will have turned itself into a sort of free clinic, so that its dignity will be broken and its prospects for doing good greatly diminished. Moreover, I very much doubt whether clergymen, by training and temperament or by experience, are admirably qualified to deal with medical subjects. The essential requirements for the clergyman is to have belief, to have faith; in other words, to be credulous, and credulity and good judgment are not necessarily interchangeable. Clergymen are good men. They are honest men. They are helpful men. They are hopeful, they are credulous, and therein lies the weakness in the work of this sort conducted by them. Mental treatment or psychotherapy should be based on modern psychology. It admits intelligent application of its methods in order to secure the normal mental action which shall be manifest in normal physical control, and above all things it depends in these nervous and mental cases in the establishment of hopeful expectancy. The successful psychotherapist is born. If the physician does not feel sure of himself he can never administer psychotherapy with any considerable success. The whole thing may be summed up in establishing hopeful expectancy, and I am devoutly thankful to the man who has scattered broadcast through this land the placard that says, "Keep Smiling."

Transitory Insanity and Its Basis

Dr. Charles W. Hitchcock, Detroit: This paper has, first, to do with the transitory insanities pleaded as a defense in criminal cases rather than with *bona fide* transitory insanity as laid down by the text-books. Second, transitory insanity is of rare, not to say, doubtful occurrence. Third, more frequent than its *bona fide* occurrence is its allegation solely as a means to the end of avoiding just responsibility for crime. Fourth, its most frequently pleaded varieties, transitory frenzy, transitory mania, emotional insanity, have but little standing among the best psychiatrists. Fifth, epileptic excitement and confusion, while admitted to occur, is often without adequate basis pleaded as a cover for crime. Sixth, it is unworthy of the expert, unable to make and define clean-cut diagnoses in these cases, to inject vague claims of insanity into such cases for the purpose of creating such doubt as will befog a jury. Seventh, medical experts should be careful to prove themselves anxious to conserve rather than to defeat the law. Eighth, the medical expert should approach such cases with an absolutely unbiased mind, reach his conclusions scientifically, take a clean-cut and firm position, and maintain it with the courage of his convictions. Ninth, if, with the crime eliminated, the case presents no adequate evidences to warrant a diagnosis of insanity, such a diagnosis should not be made, for the crime may not be of itself sole evidence to warrant such a diagnosis. Tenth, the expert, especially in cases in which transitory insanity is alleged, should zealously guard against being a party to the further increase of the disrepute into which medical expert testimony and insanity as an easy defense of crime have already come.

The Urgent Need of Operating in All Cases of Hernia

Dr. E. B. Smith, Detroit: There is urgent need of operating in all cases of hernia, but in this paper I restrict myself to the more frequent forms, namely, those of the abdominal and pelvic regions. Not all cases of reducible hernia are free from adhesions or local pathologic conditions other than the hernial opening. Adhesions around the ring are numerous. The local conditions may vary to a marked degree. The hernial opening may be small, tight, irritable, predisposing the sac to a partial or complete strangulation when forced through the opening, or the opening may be large and may be increased by the force of the additional abdominal contents pushing its way through. The glands adjacent become hypertrophied and adherent from the continued irritation of hernia. We must warn the patient that he should be on the lookout for certain symptoms which are pathognomonic of strangulation, yet there is danger of strangulation not being recognized even by the medical attendant, as there may be no sudden onset, no characteristic local pain, no nausea, no vomiting and no tenderness, but there may be expulsion of gas or even a fecal evacuation. The local complications may be such as to require a resection of portions of the omentum which increases the mortality, and very often we are forced to do a resection of the intestine which brings a high mortality. In uncomplicated cases, when the surgeon and the patient have been prepared, the percentage of recoveries should be from 98 to 100 per cent. An important factor in the early operation for hernia is the opportunity given both the surgeon and the patient for preparation. Knowing that the hernia increases in size, the complications in number and seriousness, and that a grave, if not fatal condition, must be the result, and knowing the necessity of proper preparation, why should we delay a comparatively simple operation for one of greater magnitude?

Dr. Conrad George, Jr., Ann Arbor: Intestinal resection comes up in connection with hernia, and I think as our methods of aseptic resection are perfected, the mortality will come down a little.

Dr. F. W. Robbins, Detroit: I think the profession is negligent in allowing patients with hernia to pass through their offices without strongly advising operation. Two years ago, in my service at St. Mary's Hospital, I saw three patients with hernia die simply because they were neglected. One of these was a patient who had had hernia for twenty years. He thought he could keep it back with a truss. Sometimes he did, sometimes he did not. He came to the hospital and he thought the hernia could be reduced, and that he would not have to submit to an operation. A few days later, when the man was *in extremis*, I operated on him and found some 10 feet of rotten gut, and the belly filled with a bloody, purulent secretion; the man died on the table. Within two weeks of that time I had two other hernia patients. One was a woman, with a large abdominal hernia, the other a man with a small strangulated hernia that had ulcerated through into the intestine; he died. These were poor people; they were sent to the hospital as a last resort, and a hopeless operation was undertaken. The deaths of these patients were not due to the conditions after they were admitted to the hospital, but to conditions that might have been prevented had they subjected themselves to an earlier operation. Since that time I have felt it my duty, when a patient comes into the office with a hernia, and wearing a truss, to urge operation, in consideration of the small percentage of mortality from operations conducted at the proper time.

Dr. Bayard Holmes, Chicago: I feel that if an operation will cure a hernia quickly and permanently, it ought to be done at once. The skill with which the operation is done has a great deal to do with the permanancy of the operation. When I first saw hernias operated on, the operations were frequently made in such a way as to allow the wound to close by granulation, hoping in this way to get a more permanent recovery. Since antiseptic methods have been applied to hernia, to every other surgical operation, and when they have been wisely managed, these hernias, so fas as I know, have been permanently cured. Of course, there are recurrences, especially when trusses have been worn a long time, and the abdominal wall has an enormous defect. The recurrences under these circumstances are worse possibly than the original hernia. The time to operate on a hernia is when it has begun, and when the abdominal wall has the full amount of strength, which it does have before a truss has been worn.

Dr. William K. West, Calumet: I think in these cases of abdominal section, when the involvement is large, when there has been free drainage on account of infection of the wound, when the abdominal walls are much weakened, and postoperative hernia likely to result, then it is wise on the part of the surgeon, before the patient leaves the hospital and as soon as the discharge has ceased, to prepare the wound: that is, open up the peritoneum, dissect free the fascia, unite the fascial layer, thereby adding strength to the abdominal wall, and guarding against a possible postoperative hernia.

Acute Postoperative Dilatation of the Stomach

Dr. Alexander W. Blain, Detroit: In this paper I draw the following conclusions: 1. The so-called acute dilatation of the stomach is a disease of the fore-gut, in which the upper portion of the duodenum as well as the stomach is involved. 2. We should be very cautious in entering the abdomen for ileus when the swelling is in the upper part of the abdomen, without first passing a lavage tube. 3. We should make an examination of the abdomen in all patients suffering from gas after operation, abdominal or otherwise, and not trust to the routine treatment without first making a diagnosis of the parts involved.

DISCUSSION

Dr. B. R. Corbus, Grand Rapids: I have had the opportunity of seeing two cases of postoperative acute dilatation of the stomach in the last few months. These cases were very much alike; both were referred to me by Dr. Campbell of Grand Rapids. In one case the dilatation occurred on the second day after an operation for the removal of a pus tube. The patient had a temperature of 101 F., but the attention of the physician was directed to the great distention of the abdomen. He suspected peritonitis. On examination it was found that the flanks were flat, and I was called. The woman had a pulse rate of 140, and seemed to be *in extremis*. The stomach was washed out; we got three pints of fluid, after which the pulse dropped. The next morning the temperature was normal and the woman was on the road to recovery. She had never vomited. The other case was a typical one of acute dilatation of the stomach of less severity. Many of these cases go undiagnosed, and maybe it is only after the attention of the physician is called to the subject that he diagnoses these cases correctly.

Dr. Conrad George, Jr., Ann Arbor: I am interested in gastric lavage in this condition. According to Dr. Aaron, the use of smaller quantities of fluid should be advised in washing out the stomach in these cases. It is much safer to use a smaller than a larger quantity, the idea being to introduce a small quantity, and then the whole stomach can be emptied out. This is an important part in lavage of the stomach in cases of acute dilatation, as in using too large a quantity of fluid there is danger of overdistention of the stomach and possible injury to its musculature and death from that cause.

Dr Bayard Holmes, Chicago: There has been no account taken of the enormous quantity of fluid which appears so rapidly in these cases. This large quantity is either normally secreted by the wall of the stomach, and is ordinarily poured out into the small intestine, or else it is abnormal. The quantity seems to be so large that it can hardly be normal. I do not know what the normal amount is when the pylorus is obstructed, whether the stomach fills up with three or four quarts of fluid in two or more hours or not. But the cases I have seen have been marked by an enormous quantity of fluid going into the stomach at rather short intervals. You may empty it with a stomach tube, but in a few minutes, apparently, you have to empty the stomach again. My experience does not lead me to think that relieving the stomach in this way invariably cures acute dilatation. I remember one case in which, fourteen days after operation, I made a diagnosis of acute dilatation of the stomach. In this case an operation was done on the right kidney, and so far as I know was perfectly aseptic, but in spite of the fact that the stomach was emptied frequently of large quantities of fluid and an effort made to keep up the patient's fluids by enema and transfusion, the patient died after two or three days.

Dr. Frank B. Walker, Detroit: In one case I had acute dilatation occurred at the close of an operation for shortening the round ligaments in a young woman who was otherwise in good condition. In preparing the parts preliminary to closure, the stomach pushed out through the incision; it was returned to its normal position, and the case ended satisfactorily, and otherwise there was no more difficulty than in any other case. It was a surprise to me, as it was the first case of the kind I had seen, and it occurred so soon after the operation.

Dr. Mortimer Willson, Port Huron: I have known of a number of cases of acute dilatation of the stomach after operation, and in the past, when I was engaged in general practice, I had a number of such cases after parturition, in that there was sudden distention of the stomach shortly after delivery. Contrary to those cases that have been reported, in the majority of my cases the dilatation of the stomach was not due to the accumulation of fluid, but to the formation of gas. In some there were enormous quantities of fluid. It has occurred to me that this dilatation is due to a defect in the nervous tone. In a number of cases there was an extraordinary amount of secretion, but the dilatation was due to gas.

Dr. Blain: Dilatation of the stomach is a misnomer. It is a dilatation of the fore-gut, in which the pylorus plays no part, and most of the secretion comes from the upper portion of the duodenum rather than from the gastric glands. Dr. Walker's case is rather unique, and entirely different from others that have been reported, and it brings up one thing which I think is true, namely, that the etiology of these cases is different. Undoubtedly, this dilatation of the fore-gut has many etiologic factors. We have used too much fluid in washing out the stomach in the past. A half pint of saline solution or water, the use of bicarbonate of soda, or something of that sort, is much better than to use enormous quantities. No matter how much water is used, you cannot get it all out unless you lower the head of the patient and raise the pelvis, which is an important part in the treatment.

Subphrenic Abscess

Dr. **Frank B. Walker**, Detroit: Subphrenic abscesses are observable clinically on both the right and left sides of the upper abdomen. The signs of subphrenic abscess are in the main those of suppuration elsewhere, varying according to the source and route of infection. The constitutional symptoms are pain and tenderness in the upper abdominal region, chills, fever, immobile swelling, leucocytosis, thirst, disturbed nutrition and dyspnea. The course of subphrenic abscess is that of a complication of some other abdominal infection. One or more fossæ are invaded. From statistics, it is plainly evident that operation offers by far the more favorable prognosis. This pathologic condition occurs more often than it is discovered.

Sarcoma of the Ulna

Dr. **H. E. Randall**, Flint: The types of tumors of the long bones are the osteoma, fibromata, chondromata, sarcomata and rarely myelomata. Carcinoma is secondary. The cases in the older literature of cancer were metastatic hypernephroma. The other growths not included under tumors are osteophytes, hyperostosis, exostosis, due to irritation and myositis ossificans. Tuberculosis and syphilis must be excluded. Bone cyst is a degeneration of a pre-existing tumor in most cases. Some cysts are thought to represent the entire destruction of a sarcoma. Sarcomas differ greatly in malignancy. Even early amputation does not save some patients because of the early metastases in the lungs. Bloodgood, in over 100 cases of giant-celled sarcoma, found that no metastases had occurred. These patients had been treated by curetting, resection and amputation. Curetting may be all that is necessary. A mistake that has occurred is to diagnose a small-celled sarcoma for an inflammatory condition. Multiple myeloma is incurable. These cases are recognized by the *x*-rays when but one tumor is thought to be present or by finding the Bence-Jones bodies in the urine. Several examinations of the urine may be necessary to discover the reactions. The most malignant types of sarcoma are the spindle-celled and round-celled. In one of my cases the patient was cured by removal of the ulna. The ulnar nerve must not be injured. The functional result was satisfactory and the man was able to do all kinds of farm work. I am convinced that if an early diagnosis can be made, the radius, ulna, tibia or fibula can be removed and the patient escape the more mutilating operation of amputation. The diagnosis is to be made by snipping out a piece of the tumor which is submitted to the pathologist. T. W. Huntington found that the fibula would hypertrophy to such an extent as to become virtually as strong as the tibia, in a case of destruction of the shaft of tibia by osteomyelitis.

Hydronephrosis and Pus-Producing Infections of the Urinary Tract Complicating Pregnancy

Dr. **Clara M. Davis**, Lansing, Mich.: The patient in the case which I report was a multipara, aged 23, with a family history of tuberculosis. The important points are: 1. The family history of long-standing tuberculosis in the father, and abscesses and Bright's disease, with dropsy in the mother. 2. The importance of a correct history and the difficulty of getting it in this case, owing to the fact that the patient and family had settled on a diagnosis of miscarriage. 3. The relation of the traumatism to the disappearance of the hydronephrosis and the subsequent course of the case. 4. Psychotherapeutic treatment given by the mother with the coincident disappearance of pain, the sudden appearance at about this time of large quantities of pus in the urine, showing that cessation of pain was due, not to the mental treatment, but to the free drainage of pus, and illustrating how carefully cases should be scrutinized in which mental treatments are assigned as causes of relief of pain or cure of disease. 5. The importance for diagnosis of a microscopic examination of the urine in all cases of severe abdominal or pelvic pain in pregnant women. 6. Absence of bladder involvement throughout. 7. Benign course in the absence of any but the simplest treatment. 8. Normal character of the labor which occurred at full term, and the prompt convalescence.

Uterine Fibroids; with Report of Eighty-six Cases

Dr. **Richard R. Smith**, Grand Rapids: The general purpose of the paper is to call attention to the seriousness of the disease, because of its complications, and the necessity for more radical ideas in regard to its treatment. In over half of the cases reported life or health were seriously threatened. Complications which may arise, first, from the distortion and pressure caused by increase in size; second, from the inflammatory degenerative or malignant changes which may take place within the tumor itself; third, from the external inflammatory complications, causing adhesions, abscess, etc., outside of the uterus. Hysterectomy is to be preferred to myomectomy in women who have borne children and who are approaching the menopause; or when the growths involve the uterus to such an extent as to make the leaving it a menace to good health or life. Myomectomy should be restricted generally to the simpler cases.

SIXTEENTH INTERNATIONAL MEDICAL CONGRESS

Held at Budapest, Aug. 29-Sept. 4, 1909

(Concluded from page 1130)

Disturbances of the Internal Secretions Clinically Considered

Dr. **Oliver T. Osborne**, New Haven, Conn.: Gigantism is a condition due to hypersecretion of the pituitary, and acromegaly is a condition primarily of hypersecretion, later hypersecretion of the hypophysisis cerebri. The thyroid may not only hypersecrete and hyposecrete, but the component parts of the secretion of the thyroid gland may vary in amount and in chemical constituency and cause various clinical manifestations. These symptoms and signs vary in all degrees and tendency from exophthalmic goiter on the one hand to myxedema and cretinism on the other. Insufficiency of parathyroid secretion causes tetany. A disturbed secretion of the parathyroids may cause paralysis agitans. Hypertension may be due to hypersecretion of the suprarenals. Continuous low blood pressure and neurasthenic conditions may be due to hyposecretion of the suprarenals. Continuous low blood pressure and neurasthenic conditions may be due to hyposcretion of the suprarenals. Surgical shock after abdominal operations may be due to the inhibition of suprarenal excretion. Many of the disturbing symptoms of menstruation are due to ovarian insufficiency or to increased ovarian activity, and it is doubtless probable that many nervous symptoms in women are due to ovarian disturbances. Uterine hemorrhage, profuse menstruation, and other uterine bleedings may often be stopped by the administration of mammary gland substance.

Obesity

Prof. **Carl v. Noorden**, Vienna: In the most common forms the condition is due either to over-feeding or lack of exercise, frequently these two factors are combined. It is easy to understand why excessive corpulence follows these two factors. It is much more difficult to explain those cases in which, although the proper amount of food is taken and sufficient exercise is indulged in, obesity develops. This has been termed constitutional obesity. After discussions which have been prolonged for years and after careful investigations the conclusion has now been arrived at that in such cases the oxidation power of the organism has become weakened. This is a factor which bears a direct relationship with the thyroid gland. Temporary changes in that gland raise or depress the power of oxidation. The various forms of constitutional obesity may be classified as follows: (a) primary thyreogenic obesity, dependent on actual changes in the thyroid such as atrophy, degeneration, functional weakness, and so on; (b) secondary thyreogenic obesity, that is to say, functional anomalies of the thyroid on the action of other organs, such as the pancreas, hypophysis cerebri, suprarenals, thymus, pineal gland, and perhaps other organs also, so-called chemical correlations by means of internal secretions. These questions have not only a theoretical interest but possess important bearings on therapeutics, as anomalies of metabolism known under the term of obesity can only be treated rightly, when in any given instance, the origin of these anomalies has been correctly recognized.

Polycythemia

Dr. H. Senator, Berlin: An increase in the number of red blood cells may be either relative or absolute and may occur under both physiologic and pathologic circumstances. Physiologic polycythemia is observed after the loss of much fluid from the body, after the ingestion of food rich in albumin, in convalescence from anemic disorders in new-born infants, after residence in a strange climate, and perhaps in hybernating animals during the winter months. Pathologic polycythemia is found when the blood becomes thickened during disease, in various forms of cyanosis, in certain intoxications and infections in which hemolysis takes place, and occasionally in diseases in which unknown changes in the blood occur, or in many affections of the nervous system. In all these pathologic circumstances, in addition to the relative polycythemia due to a thickening of the blood, the diminution of the tension of oxygen in the blood must be considered as a causal factor, whereby the hematopoëtic organs are stimulated to greater activity. These conditions must not be confused with polycythemia megalosplenica described by Vaquez, and polycythemia hypertamia described by Geisböch, in both of these a primary affection of the bone-marrow must be taken to be the cause of the polycythemia. Geisböch's disease, of which very few examples have been recorded, may be distinguished from that of Vaquez by the fact that in the former there is a high blood pressure together with hypertrophy of the heart, and enlargement of the spleen cannot be demonstrated. The changes in the blood, which have been more especially studied in Vaquez' diseases, consist in an increase in the viscosity of the blood, and a higher specific gravity. The resistance of the erythrocytes does not appear to differ from the normal, whilst the capacity for the absorption of oxygen lies within the usual limits, or is increased. The respiratory exchange in many cases is found to be high. With regard to treatment a vegetable diet and bleeding gives favorable results. Many cases of primary polycythemia cannot be placed under either of these categories.

Tuberculosis and the Community

Dr. S. Bernheim and Dr. L. Dieupart, Paris, said that, speaking generally, all collective work and every kind of overcrowding favored the development of tuberculosis, especially when they occurred under conditions of faulty hygiene, as was the case in the pursuit of so many occupations. They alluded to the researches which they made among laundry workers, printers, compositors, and sugar-refiners, among whom they found an excessive proportion of tuberculosis. In the same way the staffs of hospitals are often affected. Lunatics, carpenters, floor-layers, policemen, workmen, railwaymen, inmates of penitentiaries, domestic servants, soldiers, and sailors, all pay a heavy penalty to the contagium of tuberculosis. The authors discussed the causes of this contagion which they have estimated by statistical returns for each calling. The remedy which they propose is a relentless attack on unhealthy workshops, dusty trades, insanitary and dark houses, the supervision of the sanitary surroundings of the "pretuberculous" child from his schooldays onward, and the complete abolition of insanitary barracks and workshops. But the struggle against tuberculosis will never be effective unless directed by competent and independent men with a wide mandate, a free hand, and full public powers for the performance of their work. Further, they must be assisted by the serious and persistent cooperation of all classes of society and trade or professional organizations. Tuberculosis is a disease due to misery and ignorance; it plays its worst havoc among the working classes, and it can only be banished from the community by the action of the community itself.

Treatment of Paralytic Deformities in Children

Dr. Robert W. Lovett, Boston: The subject of tendon transference in paralytic deformity has been thoroughly discussed and no routine discussion of the matter is needed. The varieties of paralytic deformity are seven: (1) Deformity due to simple gravity distortion; (2) deformity due to adaptive shortening and lengthening of soft parts; (3) deformity due to the contraction of non-paralyzed limbs; (4) distortion from weight-bearing on partly paralyzed limbs; (5) deformity of the trunk due to effort to secure equilibrium; (6) bony deformity following persistent malposition, and (7) dislocation. The importance of preventing paralytic deformity is important as deformity is in nearly all cases preventable. Supporting apparatus should be used from an early period for the purpose of preventing malpositions. Treatment is, first, mechanical, and secondly, operative, both supplemented by a third therapeutic measure, the development of the muscles by muscle-training, massage, and electricity. The possibilities of mechanical stretching are: (1) The stretching of contracted tissues; (2) the shortening of lengthened tissues, and (3) the influence of growth toward normal by properly fitting apparatus. The replies to a circular of enquiry sent out to the members of the American Orthopedic Association show that tendon transference is on the whole useful, and that periosteal insertion is preferable to insertion of tendon into tendon. The after-treatment is fully as important as the operative. The treatment of paralytic deformity should consist of a combination of the three methods; the operative should not overshadow the others, and the operation of tendon transplantation in properly selected cases is to be regarded as a useful and satisfactory one.

Infantile Malaria

Dr. J. P. Cardamatis, Athens, Greece: Children at the breast are less attacked with malaria than at any other age, infants during the first year of their age enjoying a great comparative immunity. During the second year of life the liability to attack is not much increased, but between the ages of 2 and 7 years, and for some reason or other especially between the ages of 2 and 3, children are particularly subject to the poison of malaria. We are constantly led to believe the placenta to be furnished with antitoxic material which resists the development of the maternal hematozoa, destroying them at the surface of the placenta. Both among nurslings and little children there is great variation in susceptibility to malaria, the same natural immunity being met with as prevails among the indigenous inhabitants of tropical regions, though perhaps on a somewhat lower scale. Contrary to what has been affirmed by Plehn, the form of paludism which confers immunity does not always result in anemia. The natural immunity which has also been observed among children entirely differs from that relative immunity mentioned by Koch, which is due to a great frequency of infection during childhood. It differs also from that immunity which has been observed by Celli in the environs of Rome, and which is attributed to the periodical development and exhaustion of intensity of epidemics. Both the child and the adult in Greece are most frequently attacked with estivoautumnal malaria of the tertian type.

Cyclic Vomiting in Children

Dr. J. Comby, Paris, France: Periodic or cyclic vomiting occurs in attacks lasting two or more days with variable intervals; it is encountered between the ages of 2 and 6 or 8 years. It is seen a little more frequently in boys than in girls. Sometimes several members of the same family are attacked in turn. A neuroarthritic heredity is present in many cases. As pathologic conditions preceding the vomiting there may be sore-throat, adenoids, dyspepsia, a tendency to vomit, enterocolitis, and appendicitis. This form of vomiting has been ascribed to the liver and fatty acid poisoning, acidosis, and acetonemia. If in fatal cases a fatty condition of the liver has been found it is very evident that it has not been primary but secondary to digestive troubles. It is necessary to look for lesions of the appendix. The symptoms consist of uncontrollable vomiting with rapid wasting, which suggests meningitis, peritonitis, internal strangulation, or appendicitis. Constipation, fever, and acetonuria are frequent. The prognosis is generally favorable, but at least ten fatal cases have been published. After having eliminated indigestion the ingestion of some poisonous substance, migraine, intestinal obstruction, and peritonitis the appendix should be examined by an operation. Medical treatment consists of the administration of alkalies, a vegetarian diet, hydrotherapy, and saline injection. Surgical treatment consists in appendicectomy in an interval.

Diagnosis and Treatment of Tumors within the Spinal Canal

Prof. H. Oppenheim, Berlin, read a paper on this subject in which he came to the following conclusions:

1. The differential diagnosis between tumors springing from the meninges and from the spinal column itself can scarcely be said to be established. 2. For the diagnosis between intramedullary and extramedullary new growths important but not absolutely trustworthy symptoms are existent. Of these the chief is the constancy of the upper level of the lesion. Nevertheless, the collection of cerebrospinal fluid above the tumor and the frequently accompanying meningitis serosa circumscripta may cause this level apparently to vary and thereby reduce its diagnostic value. For other reasons also the upper level may seem higher than it really is. Criteria for distinguishing between meningeal tumors and spinal gliosis are not trustworthy. 3. Serous spinal meningitis presents more of the characteristics of spinal tumors than any other extramedullary disease. The aids to differential diagnosis mentioned by Sir Victor Horsley cannot always be depended on. 4. Spinal medullary "pseudotumors" are to be considered with reserve. 5. The segmental diagnosis of spinal tumors may be complicated by the existence of secondary serous or fibrous meningitis. *The symptoms of a tumor may be referable to a level below the site of the tumor.* Therapeutic results are distinctly encouraging.

The Function of the Frontal Lobes

Professor Bianchi, Naples: 1. For experimental work on the frontal lobes the only satisfactory animal is the ape, since in it these structures are well-developed and their architectural structure corresponds to that of the human cerebrum. The psychical activities of each ape must be carefully studied both before and after operation. 2. In front of the motor area (Rolandic) is an electrically excitable zone extending from the mesial margin of the hemisphere over the outer aspect to where that surface becomes continuous with the orbital surface. It is an integral part of the frontal lobe, and corresponds to the prefrontal fissure. From this area the muscles of the neck, eyes and ears can be stimulated. 3. The extirpation of the frontal lobes never produces permanent motor or sensory defects. Visual defects, similarly, are fugitive. 4. The whole intellectual life of the ape is altered after removal of the frontal lobes. Perception, attention, inhibition, and in particular memory and association, are enfeebled. The animal has no longer the power of profiting by experience. Sometimes stereotyped movements and tics are observed. 5. As a result its psychical tone is lowered; it lacks initiative, courage and spirit.

Pathology of Hereditary Diseases of the Nervous System

Dr. B. Sachs, New York: The term "family diseases" is preferable to "hereditary diseases," since very few diseases are conveyed directly from parent to child, whereas the morbid tendency exists in one or both parents which leads to the development of a family disease. There is a marked difference between the cerebral and the spinal groups; the family; diseases of cerebral origin are due to changes in the highest nerve elements, viz., the ganglion cells; the spinal affections are due largely to disease of, or maldevelopment of, one or more systems of white fibers. The one exception to this group is the spinal form of progressive msucular atrophy, and that is only rarely inherited. Family diseases of cerebral origin include hereditary diplegia, hereditary optic nerve atrophy, and amaurotic family idiocy, the infantile form (Tay-Sachs) and the juvenile form (Spielmayer and Vogt). In both types of the latter disease the ganglion cells of the entire nervous system exhibit a marked swelling of the cell body and of the dendrites, *while the axones remain intact. The active cytologic factor* is an abnormal swelling of the hyaloplasm and not a degeneration of the fibrillæ. The occurrence of the disease among Hebrews only suggests that in the members of a race whose nervous system is prone to deterioration children are born with the highest nerve cells so defective that they are entirely unequal to perform the ordinary vital function, and at a very early day undergo a typical disintegration.

Nervous and Psychical Manifestations of Arteriosclerosis

Professor von Tschisch, Dorpat, Russia: Arteriosclerotic neurasthenia is a common disease, especially between the ages of 50 and 55, characterized by anxiety and depression (in association with cardiac symptoms), insomnia, heaviness and numbness of the head, fatigability and incapacity for work. On the mental side it is distinguished by apathy, ill-humor, and irritability. From this stage the transition is a gradual one to arteriosclerotic dementia, in which the memory is greatly impaired, all psychical processes are slower, the patient becomes stupid, his opinions and judgments are mechanical and elementary, the imagination atrophies, and the will power diminishes. *According to Dr. Cramer of Göttingen* the nervous phenomena of arteriosclerosis precede the mental. The former usually consists in a triad of headache, giddiness, and defective memory, associated with, or followed by, transient pareses, slowing of speech, sluggish and unequal pupils, and paresthesia. Prominent among psychical symptoms is depression, sometimes also irritability and a paranoid symptom-complex.

Imbecility in Its Clinical and Medicolegal Aspect

Dr. Sommer, Giessen, Germany: 1. Idiots treated in institutions and the inmates of reformatory schools have many points of resemblance in bodily and mental characteristics. 2. It is therefore desirable that there should be a uniform method of investigating all such cases, and the further requirements for special groups may be easily met by a more extensive application of the special sections of the investigation schedule and by supplementary pages. 3. In studying congenital mental weakness as observed among the inmates of idiot institutions and reformatory schools a great many physiologic and psychophysical methods of examination might be usefully applied, in addition to those given in the investigation schedules, for the purpose of obtaining a better insight into the mental processes. 4. This improved system of classification is valuable both medically, psychologically, and educationally; it, moreover, leads to a better cooperation between the medical and educational authorities in general questions, as well as in respect to the special requirements of individual cases. 5. In the investigation of juvenile criminality it is to be remembered that some of the inmates of reformatory schools are obviously imbecile; when these are left out of consideration it will be found that the ordinary methods of investigation often fail, while, on the other hand, in individuals with apparently normal mental condition, more particularly as regards the intellectual faculties, there are apt to be hysterical and epileptoid manifestations as well as congenital moral defects. 6. Possession of the mental evidence of the existence of power requisite for comprehending the culpability of an act is a bad sign in a juvenile offender. 7. When juvenile offenders are of apparently normal mental capacity, the investigation respectively of their environment and of their inherited characteristics in connection with the study of family circumstances often leads to the recognition of the external or internal sources of criminality. 8. It is probable that analysis of the external and internal influences will more and more tend to show that juvenile crime both in its individual and in its social relations is to be regarded as a disease.

Imbecility in Its Clinical and Medicolegal Aspect

Dr. W. Weygandt, Hamburg, Germany: There are only a few places in which lunacy practice takes cognizance of the ideal classification of anomalous mental conditions, the study of psychologic distinctions with appreciation of bodily peculiarities and special features in the progress of the cases, subsequently confirmed by the results of post-mortem examination. Nevertheless, in the least esteemed branch of psychologic medicine, the investigation of feeble-mindedness in children, science is continually advancing toward this ideal, inasmuch as it obtains increasing success in separating from the mass of complex phenomena a number of groups which exhibit features entitling them to be regarded as distinct clinical entities. The groups which at present are more or less sharply defined are amaurotic idiocy in members of a family, and imbecility associated (1) with abnormal states of the thyroid body, (2) with encephalitis (porencephaly, atrophic sclerosis, etc.) (3) with hydrocephalus, (4) with meningitis, (5) with the mongolian type of features, and (6) with epilepsy; to these must be added tuberculous sclerosis, dementia infantilis, dementia præcox, and the group due to embryonic inhibition of cerebral development. Besides these there are cases which can not yet be clinically differentiated into special classes, and which, more particularly in slight degrees of mental defect, cannot be precisely classified during life. Hysteria, neurasthenia, and melancholia are mental conditions deserving attention. In arriving at practical conclusions such as are required in judicial decisions and in questions connected with the administrative protection of imbeciles the first thing to be considered is the special nature of the defect, because the various groups exhibit varying degrees of unfitness for general society and also of capability for being influenced. The second and even more important point is the degree of the defect. For instance, epilepsy is of itself a disease of the greatest importance in connection with crime; in the worst cases, however, the patients are unfit to be at large. The severe cases are of minor importance from a medical point of view, whereas the mild ones devoid of special characteristics are practically far more important, and psychoneurotic cases are most important of all. The earlier we can recognize an individual as defective in a material degree and the earlier we can draw legitimate inferences as to the person's mental capacity and suitability for institutional treatment, the more positively can it be referred to a definite group in accordance with clinical and still more in accordance with bodily peculiarities. In estimating the degree of feeble-mindedness the intellectual level of the person's environment must be kept in mind, and the same precaution should be observed even in the case of law-breakers who have not incurred any suspicion of mental defect. In answering a question as to a person's capacity for forming an opinion the most practical course is to endeavor to compare the case with a normal child at a definite age-period; of course with due regard to any anomalies external to the intellectual sphere. The proper treatment of a criminal imbecile is a matter for physicians and sociologists.

Diagnosis and Treatment of Mediastinal Tumors

Dr. A. Ceccherelli, Parma, Italy: Mediastinal tumors are possible of diagnosis, but only by the use of all our modern methods, foremost among which we must put radioscopy. No means of investigation must be neglected because it is only on an accurate and positive diagnosis that the decision to perform a difficult and dangerous operation can properly be based, an operation which too often results in a speedy recurrence, the tumor or the infected glands not having been completely cleared away. Tumors of the anterior mediastinum are most promising to attack surgically when they spring from the bones, for the invasion of the mediastinum is only secondary. Surgical intervention is possible in tumors of the posterior mediastinum if the tumor is esophageal, for if it is limited to three centimeters in extent it can be resected and the cut ends of the esophagus brought together, while if it is more extensive the two ends can be brought up to the wall of the thorax or they can both be sutured and the lower end invaginated into the stomach, a gastrotomy being subsequently performed or a plastic operation on the esophagus can be performed. If the posterior mediastinum has to be reached it is better to do so by the transmediastinal route, and it is better to approach the tumor from the right side of the thorax especially if it is low down. A longitudinal incision is to be preferred, and a transverse one may be added to form a flap, resecting a certain number of ribs in order to allow the surgeon a better view of the field of operation.

Relief of the Eye Disease in Egypt

Mr. A. F. MacCallan, M.B., B.C. (Camb.), F.R.C.S. (Eng.), chief inspector of ophthalmic hospitals in Egypt and late senior house surgeon and late chief clinical assistant at the Royal London Ophthalmic Hospital, Moorfields, read an interesting paper on this subject in which he considered mainly the incidence of blindness and trachoma. He divides the clinical variety of trachoma seen in Egypt into four stages based on the comparative prominence of the three features of the disease, granulations, papillary hypertrophy, and connective tissue formation. The universality of trachoma in Egypt is instanced by the high percentage of pupils in the government primary schools affected with the disease, 96 per cent. at one of them. According to the census of 1907, half a million persons were enumerated as blind in one or both eyes, this figure is probably a quarter of a million short of the actual number. Ophthalmic conditions have enormously improved in Egypt during the last twenty years, but no explanation has been offered for this phenomenon. The generosity of an Englishman enabled the Egyptian government to equip and maintain two traveling hospitals which were originally organized six years ago by MacCallan. In addition to these he has the direction of three permanent hospitals in different provinces recently built, or being built, partially by charitable effort and partly by the government. Mr. MacCallan travels from one to another of these five hospitals, of which he is director, and at which he gives clinical instruction to Egyptian surgeons who have obtained their diplomas at the government medical school. The surgical staff of all the hospitals is composed of surgeons thus trained.

Fibroids of the Uterus and Pregnancy

Professor S. Pozzi pointed out that under the influence of pregnancy fibroids of the uterus may undergo an important series of modifications as regards size and position. It is generally taught that fibroids become enlarged during pregnancy, but this is very variable. In some cases these tumors undergo during pregnancy a rapid and remarkable increase in size. The enlargement of a fibroid tumor concurrently with pregnancy is usually due to edematous infiltration, but it may be caused by actual hypertrophy of the tumor elements which produce a more or less marked softening of the whole growth. In other cases aseptic necrosis takes place, but more often cystic degeneration occurs, while rarely suppuration and gangrene of the tumor are seen. During pregnancy there is a tendency for pelvic fibroids to rise up out of the pelvis, but at times this does not occur and in such cases there may be obstruction to delivery. In many cases, fibroids do not in any way interfere with the normal course of the gestation. Occasionally, however, acidents of considerable gravity occur. Among these are incarceration of the retroverted gravid uterus, especially likely to take place at the fourth month and very frequent with an intraligamentous fibroid. When the tumor either by its weight or its position exercises pressure on the walls of the bony pelvis pressure symptoms are liable to supervene. These may take the form of pain due to compression of the nerves, dysuria, retention of urine, albuminuria, pyelonephritis, constipation, or distention from pressure on the intestines. In some cases, attacks of pelvic peritonitis are set up and may require immediate operation. In rare instances torsion of the pedicle, or even of the whole uterus, may be encountered with acute symptoms simulating those seen in cases of torsion of the pedicle of an ovarian cyst. Further effects of the fibroid on the pregnancy are noted in the occasional occurrence of antepartum hemorrhage, abortion, death of the fetus, and its retention *in utero.* Diagnosis of a fibroid complicating pregnancy may be simple or difficult. Three conditions may arise: the medical attendant may be aware that his patient has a fibroid and may find evidence of the occurrence of pregnancy, or he may know nothing of the patient and may find a fibroid with symptoms and physical signs indicating the presence of a pregnancy as well. In other cases, the signs of a pregnancy may be evident, but there may be others less certain pointing to the presence of fibroid. In such a case the diagnosis may present difficulties, and the condition is very likely to be regarded as one of extrauterine gestation. In the majority of patients the pregnancy runs its normal course, even when a fibroid is present and no interference of any kind is required. Any operative interference is only permissible during pregnancy when some grave complication supervenes, such as marked pressure symptoms, vomiting, severe pain, or peritonitis. In any case, even when it is certain that the presence of the fibroid will not permit of a natural confinement it is necessary to await the arrival of full term and then to perform Cesarean section. In cases in which the obstetrician is compelled to intervene in the course of the pregnancy the best treatment is to perform, whenever possible, myomectomy, either vaginal or abdominal. The induction of abortion or of premature labor are both contraindicated, and when myomectomy is not possible then the only alternative in these patients is hysterectomy.

Imbecility in its Clinical and Medicolegal Aspect

DR. FISCHER. Budapest, took for his subject that form of imbecility which has been described under the names of moral insanity or moral imbecility. The most important symptoms, he said, were the following ones: Lack of discretion, absolute incapacity for being influenced, strong propensity traceable even to childhood, lifelong instability and restlessness, aversion to useful employment, unsociableness, exaggerated self-esteem, excessive fancifulness, vanity, complete want of ethical ideas and impulses, absolute unconsciousness of justice and morality, and a great many signs of degeneration. Heredity had something to do with the development of these defects. Observations extending over many years had convinced Dr. Fischer that the ethical imperfections enumerated in this list and the criminal acts arising therefrom were the result of mental incapacity dating from the earliest period of life. In all individuals whom he had had the opportunity of observing from the age of 10 or 12 years to full maturity he found that the ethical shortcomings which rendered them useless as members of society showed no tendency to increase. He then described those forms of the disease which presented similar symptoms, and might therefore be confused with moral imbecility, called attention to the chief points serving to distinguish them, made some remarks on the prognosis, discussed the general question of how such cases should be dealt with, and devoted a few words to the subject of judicial decisions. He agreed with Songard that this form of mental abnormality—imbecility—presented certain features which were always similar and decidedly characteristic; as already mentioned, the features in question existed from the earliest period of life and showed no tendency to increase. On account of possessing these qualities the condition now described might be reckoned as one of the special or definite types of mental disease.

The Control of the Milk Supply in Large Towns

DR. M. BALLO, Budapest, said that the official examination of milk delivered for consumption in large towns is subject to extraordinary, often almost insuperable, difficulties. Since the composition—that is to say, the amount of valuable elements contained in it—is subject to great variation in natural milk, and since, according to most regulations, the composition of the weakest, that is, the milk that is poorest in such elements, is used as the foundation for the examination, it is obvious that a richer milk can be adulterated or diluted to a certain degree so as to appear as weak, yet not adulterated milk, and be thus offered for consumption. In any such case, it is only possible to decide whether the milk is naturally weak or is more or less adulterated with water by means of tests undertaken regularly at the farms, and this is impracticable for large towns which draw their milk from many and various sources, unless by means of control of all dairy farms and milk depots. But since such continual control would entail much expense, the question arises as to whether it would not be simpler and more effectual to prescribe as the minimum standard a richer average milk instead of the weakest natural milk as at present. The latter proceeding would appear the most suitable, for the purveyors of weak milk would certainly lose the trade in large towns if they were not in a position to provide a supply of rich milk, but the sanctioning of a possible watering of milk would be thereby avoided in the surest and simplest way.

Tuberculosis in Armies

DR. C. SFORZA, Rome: Tuberculosis, generally speaking, is diminishing in all armies. Its incidence is always more marked during the first years of soldiers in the ranks. In armies tuberculosis is generally an important disease, proceeding from the revival of old and latent foci existing at the time of admission to the service. In order to reduce the number of cases and of deaths from tuberculosis it is necessary to eliminate all tuberculous and predisposed subjects on entry to the army; to gradually improve the strength and the power of resisting fatigue of the recruits, especially those whose constitution is weak, and those who have a bad heredity; to avoid as far as possible the contraction of the disease by soldiers during their service, and to eliminate promptly all cases of tuberculosis which arise. Patients with the disease, whether curable or incurable, would have to be treated in civil or military sanatoriums at the expense of the state, because armies, while protecting soldiers from tuberculous infection, must not spread the disease among the civilian population. On leaving a sanatorium the patient could receive an annual or temporary indemnity, according to the degree of incapacity at the time.

Dementia Præcox and Military Service

DR. DRASTICH, Vienna: Great importance attaches to dementia præcox in military matters. For it occurs relatively often among the men and also in isolated cases among the younger officers. Since it often develops gradually, even imperceptibly, it is not infrequently overlooked in the early stages. It occasionally leads to various conflicts with discipline and military penal law, and, moreover, to occasional punishment or ill-treatment of those suffering from the disease, and at times it shows symptoms which may easily be mistaken for simulation. For these reasons it is important that not only military surgeons but also military judges should possess as exact a knowledge as possible of this form of psychic derangement, and especially that they should know the symptoms with which the disease is frequently marked at the beginning. Also the knowledge that dementia præcox often takes an intermittent course and has rather long intervals of quiescence is most important and essential in regard to anamnesia, for the assessment of the data relating to the history, and also for the claims of maintenance which come under consideration.

The Treatment of Amebic Dysentery with Special Reference to Appendicostomy

DR. JAMES M. ANDERS and DR. WILLIAM L. RODMAN, Philadelphia: The subject of the treatment of amebic dysentery, particularly in its bearings on surgical procedures, assumes importance in view of the utter helplessness of a certain proportion of cases which have been allowed to drag on until the patients no longer yield to medical treatment, and also because accessible statistics indicate clearly the widespread prevalence of the disease even in subtropical and temperate regions. The fact that an unsterilized water-supply is the principal source of infection deserves especial emphasis. The danger of eating green vegetables and fruits which have either been fertilized by the oriental method, i. e., with human excrement, or cleansed with contaminated water, must be recollected. In the treatment of the attack an important indication to be fulfilled is rest. Magnesium sulphate is recommended since it lessens the pain and tenesmus by removing the hardened fecal masses and inhibiting rather than exciting undue peristalsis. In the advanced stages of amebic dysentery and in cases manifesting highly acute invasion symptoms, purgatives may assume the rôle of aggravating causes. Ipecacuanha early gained popular favor only to fall from its enviable position with the passing of time. It was reintroduced by Sir Patrick Manson, who has expressed the belief that in this drug we have a remedy possessing specific virtues. In general, but not invariably, it exerts a markedly beneficial effect, causing the amebas to disappear rapidly from the dejecta. Much stress is placed on the improved mode of administration by means of "membroids" and salol-coated pills. We think it may be questioned whether chronic irrigation *per se*,—*i. e.*, without surgical intervention, has in its last analysis given more encouraging results than the ipecacuanha treatment properly employed. The simple fact is that not all cases of chronic amebic dysentery yield to either rectal lavage or ipecacuanha even though carried out with great thoroughness. It is desired to place on record a case in which appendicostomy followed by irrigations with a solution of quinin resulted in a remarkable cure. We favor doing the operation in two stages, believing that it is best not to open the appendix until firm adhesions have taken place between the cecum and parietal peritoneum. If the mesoappendix is ligated the blood-supply to the appendix is cut off and gangrene is almost certain to follow. Bring the base of the appendix well up against the abdominal wall, stitching the mesoappendix to the parietal peritoneum. The appendix is snipped off with a pair of scissors after brushing it over with a solution of cocain. As compared with cecostomy we unhesitatingly pronounce in favor of appendicostomy, since it is impossible to prevent leakage after the former operation. It is our belief that the fistula should, as a rule, be maintained indefinitely if the patient contemplate residence or travel in a tropical country. Closure of the fistula is most easily accomplished when desirable.

Medicolegal

Liability for Leaving Sponge in Abdomen

The Court of Appeals of Kentucky says, in Samuels vs. Willis (118 S. W. R. 339), a malpractice case, that the defendant was a surgeon of many years' experience in performing abdominal operations. He was called to operate on the plaintiff for ovaritis. He sent down a trained nurse and followed the next day with a medical student as assistant. Several physicians of the neighborhood came in to witness the operation. After the patient had been put under the influence of an anesthetic, the abdomen was opened by a five or six inch incision, the intestines were pressed aside from the infected region, and in order that they might be held in place, and so as not to interfere with the operator's work, a number of surgical sponges were inserted in the abdominal cavity, forming a kind of cofferdam about the organ to be operated on. These sponges were described as gauze cloths about 14 inches by 6 inches, stitched together. After the operation the sponges were intended to be removed and the cut in the abdomen drawn together by stitches, leaving a small opening in which was inserted strips of the gauze for drainage purposes.

The operation was thought to have been a success, but the patient did not respond by the anticipated recovery. Instead, after a few days, she grew worse. Finally, and in about thirty days after the operation, it was discovered through a part of the original opening made in the abdomen, that some foreign substance was lying near the surface, which on being removed was discovered to be one of the surgical sponges used at the operation. So it was claimed by the plaintiff. It was incrustated in and saturated with foul-smelling pus. After its removal the patient improved in health, but there was left a sinus, which it was claimed had developed into a fecal fistula.

This suit was brought, the plaintiff charging malpractice in that the defendant negligently left or suffered to be left in her person after the operation the surgical sponge, which irritated the intestines, causing them to fester and ulcerate, creating the fistula, which emitted fecal matter and noxious gases to the serious impairment of her health, and causing her sickness and humiliation, mental and physical suffering, for which she sought damages. Simplified, the charge in the original petition was that the defendant had carelessly left foreign substances in the plaintiff's abdomen after the operation, which had perforated her bowels, producing the ill effects specified. But it was doubtless thought by the plaintiff's counsel on reflection that they would be held to show a perforation in order to recover, and that by the foreign substance left there, whether the sponge or other thing; that to perforate required a cut or puncture. Unwilling to rest their case on such a narrow charge, they by amendment sought to and did enlarge it. First they withdrew the charge that by the substances left in the abdomen the bowels had been perforated. In lieu they charged: First, that the defendant in the course of the operation negligently cut or perforated her intestines; and, second, that the sponge which he negligently left in her abdomen ulcerated her intestines "and left an opening therein," festering and gathering pus in her bowels.

When the evidence failed to support the first charge made in the amendment, the plaintiff was still at liberty to sustain the second, if she could, and such was the issue presented by the pleadings. Proof on that issue was admitted from each side. Expert witnesses were brought from great distances by the defendant, whose testimony in the main, if not wholly, was on that point. The jury's attention was directed sharply to that issue of fact. Motions for a peremptory instruction for the defendant and for judgment on the pleadings were properly overruled.

While the defendant was testifying he was required on cross-examination to answer the question whether he carried a policy of insurance against accidents of that kind. Before another witness had been introduced the trial judge receded from his ruling on that point. Moreover, on his re-examination before the matter was withdrawn the defendant was questioned thus: "You have been asked about insurance against suits for malpractice. I will ask you if the terms of your policy cover any damages that may be recovered in a case like this?" His answer was: "Not in the slightest." The court sees no cause to suspect that the jury would have disregarded the witness' answer, or did not obey the subsequent admonition of the judge. The error was probably harmless in the first place, and was cured in the next.

The defendant testified, and a number of other witnesses in his behalf testified, as to the customary and correct method of skilled physicians in performing the operation which was the subject of this suit. Some of the witnesses were asked the hypothetical question whether, if the operation was performed in that manner, it was an ordinarily careful manner of doing it, or was negligent. On objection the witnesses were not allowed to answer that question. This was the correct ruling. That was for the jury alone. Witnesses from a profession may be called to testify concerning the teachings of their science, and the customs of their craft, but whether these things amount to due care is for the court or jury to say in a controverted case.

Many of the physicians testifying on behalf of the defendant said that the best of surgeons left a sponge or some foreign substance in the bodies of their patients in performing similar operations. It was argued from this that, as the highest degree of skill and care are not exempt from the commission of such accidents, a similar lapse by the defendant was at least not other than "ordinary care;" but that did not follow. Because all men are at some time careless does not relieve any man from the legal consequences of his careless act; but even that was for the jury to say whether the defendant exercised the degree of care in the case which ordinarily prudent and skilled surgeons, who practice in similar localities, usually exercise in such matters.

The evidence was conflicting whether the defendant left the sponge in the plaintiff's body, but it was there. Its presence was not otherwise accounted for. He alone placed and removed the sponges that were used in the operation. There was considerable evidence tending to show it was left there by the defendant, and that he did not pursue the course which his own witnesses of his profession said was customary and necessary to verify whether all sponges had been removed.

The trial resulted in a verdict and judgment for $3,500 for the plaintiff. The court thinks that a statement of the case disposed of the claim that the damages were excessive, and it affirms the judgment.

Burden of Proof and Presumptions in Abortion Cases

The Supreme Court of Utah says, in the case of State vs. Wells (100 Pac. R. 681), that the statute of that state is that "every person who provides, supplies or administers to any pregnant woman, or procures any such woman to take any medicine, drug or substance, or uses or employs any instrument or other means whatever, with intent thereby to procure the miscarriage of such woman, unless the same is necessary to preserve her life, is punishable," etc. Under such a statute as this the authorities generally hold, and the court thinks correctly, that it is essential for the state to allege and prove that the production of the miscarriage was not necessary to save the woman's life, and that the burden of proving such fact is on the state.

The authorities are also to the effect that, when it is shown that the woman was healthy and in a normal condition, and that medicine was administered to her, or an operation performed on her to produce a miscarriage, the evidence is sufficient to raise the inference, and to find the fact, that the production of the miscarriage was not necessary to save the woman's life, or that it is sufficient where it is shown that there was nothing in the condition of the woman to indicate any necessity for a produced miscarriage, and that the negative in the information need not be shown by direct or positive evidence, but may be shown by circumstantial evidence. It is not enough however, that circumstances be proved from which an inference may be deduced that the production of the miscarriage was not necessary to preserve the life of the woman, but they must also be inconsistent with every other reasonable conclusion.

If an operation to produce a miscarriage is performed on a woman of ordinary good health and of normal physical conditions, the performance of such an operation is inconsistent with the conclusion that it is necessary to preserve her life. But in such case the good health and physical conditions of the woman may not be presumed, in the absence of testimony tending to show them, for the rule is also well settled that, "where circumstantial evidence is relied on, the circumstances must be proved, and not themselves presumed."

The fact that the woman was unmarried does not tend to show that the operation was not necessary to save her life any more than if she had been married. If any presumptions at all are to be indulged, it is more likely, for various reasons, that it might be more necessary, in order to preserve the life of the woman, to perform such an operation on an unmarried than on a married woman.

Nor does the fact that the defendant had illicit sexual intercourse with the woman necessarily agree with and support the conclusion that the operation was not necessary to preserve her life. If, because of the woman's condition of ill health, or other physical conditions, or bodily ailment, such an operation became necessary to save her life, it was just as necessary to perform the operation whether the woman was pregnant by the defendant or by another.

2. **Freedom of Medical Research.**—Cannon reviews the work that has been done by the Council on the Defence of Medical Research of the American Medical Association. This Council is composed of representatives of various medical sciences, who live in well-separated parts of the country. During the past year the Council has been actively investigating the conditions of animal experimentation in laboratories throughout the United States, has taken precautions against the abuse of animal experimentation and against misconceptions of the conditions and purposes of medical research, and has planned a series of papers by experts which will serve to diffuse information regarding laboratory procedures and the results of laboratory study of disease.

In order to learn the conditions of medical research, a circular was sent to all the most prominent schools; reports have been returned for more than eighty. In this circular questions were asked as to the approximate number of different kinds of animals used each year; the methods of securing these animals; the number of dogs and cats killed in the city merely to dispose of the excess; the care of animals in the medical school, including the ventilation, warmth, cleanliness and lighting of their rooms; whether operations likely to involve pain were always performed under anesthesia; whether students were permitted to carry on independent investigation or were cautioned against it; whether experimental work was conducted under rules; and whether any public hostility to animal experimentation existed in the community. These questions have been fully answered. In a large number of laboratories dogs and cats are secured from the city pound or the city police, and in some schools owners contribute animals to be destroyed. In one instance animals are reported as being obtained from officers of the humane society, who had investigated the laboratories and had become convinced that the animals are humanely treated. The accommodations for experimental animals are reported as being well-lighted, well-ventilated, properly warmed and clean; in many instances special animal houses have been built, and in five instances a special attendant is provided to care for the rooms and their occupants.

In answer to the question whether any cutting operations on unanesthetized animals are performed, all the schools that use animals have reported "No." The number of schools in which animals are kept alive after operation are very few. From these schools the testimony is uniform that hospital after-care is always given to avoid discomfort. There is absolutely uniform testimony that students are supervised in any work which they do on animals, and, in fact, are not permitted to perform any experiments, except in a few of the laboratories, on any animals other than frogs.

4. **Laboratory Work by the Country Physician.**—Cummings urges that every practitioner should own or have access to a microscope with oil-immersion lens, and as he uses this from time to time he will find his facility increasing, and with that facility a greater satisfaction in his ability to do better work. Bacteriologic work may also be done, as in examining sore throats. By keeping on hand a few culture tubes, which may be obtained at small expense from some of the medical supply houses, and also sterile swabs, one can take a culture from a suspected throat, and after keeping it in a warm place for from twelve to eighteen hours, there will be a sufficient growth to make a smear on a slide. This may be stained with Loeffler's blue, and on examination through the oil-immersion lens, will show the presence or absence of bacilli. In the matter of examination of the blood, one does not need to be specially expert to determine roughly the hemoglobin by the Tallquist scale, or the contour and relative size of the red corpuscles and presence of white corpuscles in unusual number by means of the Leishman-Wright stain, all of which may be done in ten minutes. The same stain will bring out the plasmodium of malaria if it is present. The determination of the character of tissue changes and of the chemical and bacterial content of fluids, as well as the preparation of sera and vaccines, must be left to the expert.

5. **Suppurative Pericystitis.**—Suppurative pericystitis is a somewhat uncommon condition in which suppuration takes place in the zone of loose tissue above the bladder, and in which either a part or the whole of the space of Retzius becomes a veritable abscess cavity. Chute found that in a large proportion of cases the infection is secondary to some disease of the lower urinary tract. The infection of the prevesical space takes place by direct extension, or through the lymphatics. In a considerable number of cases of suppurative pericystitis the infection is through the blood stream and may come from a focus existing in practically any part of the body. In some instances the disease is an extension from a neighboring intra-abdominal or intrapelvic lesion. The char-

acteristic thing diagnostically is the presence of a mass above the pubes that more or less closely resembles a full bladder, but that is unaffected by passing a catheter. The disease is one that will probably always have a considerable mortality. It is of a secondary character and its mortality will depend largely on the nature of the disease that it is secondary to. The treatment should be free drainage of the pus collection. Chute reports one case.

13 *Re-naming of Malaria—Anophelesis (?) E. W. Robertson, Onancock.

13. **Anophelesis.**—Robertson considers the term malaria a misnomer. The anopheles is the *sine qua non* of the disease called "malaria." It digests the parasite or "develops" it in its body. It becomes its property—a part of its body; it is a harmless germ to it, becoming physiologic like the viper's venom in his own body, but it becomes pathologic to mankind, after being bitten with almost a mathematical precision, when a train of fever and blood havoc supervenes. Therefore, he asks, why not accept the term "anophelesis?"

15. **Skin Grafting.**—Davis' paper is based on a review of 544 cases in which skin-grafting was done in the clinic of Dr. Halsted at the Johns Hopkins Hospital. In this series all types of grafts have been used and skin defects on almost every part of the body have been grafted. It was found that the general health of the patient must be taken into consideration when skin grafting is contemplated and grafts to be successful must only be transplanted to healthy wounds. As a rule, grafts do not take well on luetic individuals. No antiseptics must touch the flaps before or after cutting. A general anesthetic is necessary in the majority of cases in which large grafts are removed. It is best to cover the defect with a single large graft, if possible, as the healing is just as satisfactory as if several small flaps were used and the scar is much smaller. Silver foil immediately over the graft has proved its worth, but it is best to apply it without the paper and not to use alcohol. Temporary moist salt gauze dressings are also satisfactory. Grafting, even if only partially successful, in the majority of cases will shorten the time in the hospital and accelerate final healing. Partial grafting nearly always stimulates epidermal growth from the edges of the wound.

Autodermic grafts take somewhat better than isodermic, but isodermic grafts are much more successful than is generally supposed. When a black superficial graft is applied to a defect on a white person the pigment disappears sooner or later, and *vice versa.* The majority of Thiersch grafts, especially in breast cases, that Davis has examined, were still adherent throughout the greater part of their extent. The shrinkage in the size of a wound after grafting is in some cases quite remarkable. Contraction is prevented to a large extent by grafting, although it sometimes occurs, especially under Thiersch grafts on exposed positions, such as the palm of the hand. In such locations the whole thickness of the skin should be transplanted. Slough of the axillary flap in breast cases has little effect on the healing of the grafts, as in many of the complete "takes" there was slough of the flap, and in many of the partial "takes" there was no slough. Mild wound infection, such as pyocyaneus, seems to have little effect on the ultimate healing of the graft.

18. **Carcinoma of the Cecum.**—Smith reports two cases treated successfully by resection of the cecum. He says that in the future he will choose for the operation in resecting the cecum for removable carcinoma, inversion of both ends of the cut intestine followed by lateral anastomosis by the clamp method between the stumps, or between the stump of the ileum and the most accessible portion of the colon, preferably the ascending or transverse colon.

19. **Resection of Colon.**—Gibbon reports 10 cases which he summarizes as follows: 1. Acute intestinal obstruction; carcinoma of colon; thoracic aneurism and chronic endocarditis. Resection of descending colon and immediate anastomosis. Sudden death eight hours later. 2. Acute intestinal obstruction; adenocarcinoma of colon. Resection and immediate anastomosis. Death twenty-three days after operation. 3. Partial obstruction and carcinoma of transverse colon and sigmoid. Resection of transverse and descending colon; immediate anastomosis. Recovery; patient well to-day. 4. Tuberculous strictures of ileum; tuberculous peritonitis. Resection of ileum and cecum, Sept. 28, 1905. Second operation, Jan. 20, 1906, for fecal fistula. Lateral anastomosis of ileum and transverse colon. Third operation, January, 1907, same condition; lateral anastomosis of ileum and sigmoid. Fourth operation, May 1, 1907; resection of transverse colon with a portion of the ileum. Fifth operation, May 19, 1907; jejunostomy. Patient died May 21, 1907, twenty months after first operation. 5. Obstruction of bowels due to carcinoma of sigmoid. Operation; colostomy, and eight days later resection and anastomosis. Recovery, with death from recurrence one year later. 6. Carcinoma of appendix and cecum. Resection of cecum, lateral anastomosis, Oct. 5, 1907. Death on seventh day after operation. 7. Carcinoma of ascending colon, March 28, 1908. Recovery; well at the present time. 8. Acute intestinal obstruction due to carcinoma of splenic flexure. Colostomy, May 12, 1908, followed by resection May 20, 1908. Death June 6, 1908. 9. Tuberculosis of cecum and peritoneum. Resection of cecum. Recovery; well to-day. 10. Carcinoma of sigmoid. Resection and immediate anastomosis, Jan. 31, 1909. Death, Feb. 14, 1909.

36 *Tuberculin-Treated Guinea-Pigs in Recognition of Tuberculosis. G. Ebright, San Francisco.

28. **Bilateral Cystic Kidneys.**—A careful study of three personal cases and of others recorded in the literature convinces

Krotoszyner that polycystic degeneration of the kidneys is in almost all instances a bilateral affection. In cases in which, for the time being, one kidney appears to be anatomically and functionally healthy, an involvement of this organ may be expected to develop later. Determination of the kidney function is indispensable prior to decision on any operative procedure. Nephrectomy in cystic kidney is always contraindicated. Excruciating pain, general sepsis caused by suppuration of cysts, profuse hematuria, and distressing symptoms due to the presence of enormously large cysts are, under favorable conditions (good renal function), indications for operative interference. Nephrotomy with puncture of cysts, decapsulation and nephrofixation are the operative procedures which in selected cases may give satisfactory (temporary) results.

29. **Value of Wassermann Reaction.**—From a study of 36 cases of cardiac and vascular disease, the importance of syphilis as a causative factor is established in a very large percentage of all the cases. The highest percentage was obtained in cases of aneurism, in which a positive Wassermann reaction was obtained in all of 5 cases. In the cases of aortic disease, 10 out of 13 cases gave a strongly positive reaction; 2 gave a weak positive reaction. In marked contrast to this are the cases of diffuse chronic endocarditis affecting the mitral valve in which only 1 of the 7 cases gave a positive reaction. Collins and Sachs believe that the inference is justified that rheumatic and other infectious agencies are a much more potent etiologic factor in diffuse chronic endocarditis than is syphilis. Taking all these facts into consideration, there can be little doubt that when we have pronounced symptoms of aneurism or of aortic disease, it is well to suspect syphilis, even though the manifestations may be latent. Even in those cases in which articular rheumatism and other infectious agents may have played some sort of rôle, and in which metallic poison or abuse of alcohol or of nicotin be admitted, if a Wassermann reaction gives positive results, antisyphilitic treatment should be instituted, whatever else may have been discovered regarding the antecedent history of the patient. No doubt articular rheumatism and syphilis occur often enough in one and the same individual, and if the course of antisyphilitic treatment has been decided on, we may at least ask that it be properly administered. Collins and Sachs favor the routine treatment by hypodermic injection of mercury. Their best results have been obtained by the use of deep injections of corrosive sublimate. In some cases marked improvement in the cardiac and vascular symptoms followed on such treatment, but even if the vascular system should not improve the mercurial treatment, a positive Wassermann reaction would justify vigorous specific treatment for the purpose of preventing serious syphilitic involvement of other organs and systems of the body.

31. **Leprosy.**—Heiser has employed the x-ray successfully in a few cases, but does not regard it as being suitable as a routine treatment. The cases in which this form of treatment is apparently of value are the early stages of the tuberculous type in young and otherwise healthy subjects. The breaking down by the x-rays of one large, leprous granuloma of an individual usually results in marked coincident improvement in the granulomas situated in parts of the body far removed, and to which the x-rays have not been applied. The experience in the Philippines during the past three years demonstrates that segregation has decreased the incidence of leprosy by over 50 per cent.

35. Abstracted in The Journal, June 19, 1909, p. 2017.

36. **Tuberculin Reaction in Guinea-Pigs.**—The experiments on which Ebright's paper is based were undertaken in order to determine to what extent the tuberculin reaction in guinea-pigs might be of value in the diagnosis of human tuberculosis. The problem which presented itself was to reduce the length of time required for the determination of tuberculosis in guinea-pigs that had been inoculated with material containing tubercle bacilli. The method employed in carrying out this test has simplicity to commend it and the fact that positive results are conclusive. The technic consists of making an emulsion of the suspected material in normal salt solution, if it is not already fluid enough to be injected through a coarse syringe or sharp-pointed, improvised pipette. Three guinea-pigs are inoculated by injecting a considerable quantity under the skin of the abdomen. At the end of six days one pig is given 0.25 c.c. of tuberculin hypodermically on the other side of the abdomen, and is chloroformed at the end of twenty-four hours and autopsied. The fluids at the site of the original inoculation are smeared on a slide and examined in the ordinary way for tubercle bacilli. If the first pig results negatively, another is examined in the same way by giving tuberculin at the end of two weeks, and making the autopsy at the end of twenty-four hours. If this is also negative, the third pig is given tuberculin at the end of from four to six weeks, and the result of its examination is a check on the first two. The test offers a means in a considerable proportion of cases, of making a diagnosis at the end of a week instead of waiting until the lapse of from four to eight weeks. It also presents a method of distinguishing tubercle bacilli from other acid-fast bacilli, especially when, as often happens, they are present in large numbers.

41. **Decomposition of β-Oxybutyric Acid.**—The experiments of Wakeman and Dakin show that β-oxybutyric acid is oxidized by means of material derived from the liver, but not containing the liver cells. The oxidizing power of such material is destroyed by heating; hence it is concluded that the oxidation is due to a ferment contained in the liver tissue. The results also show clearly that an enzyme capable of decomposing aceto-acetic acid is also present in normal liver tissue, and that this action is not increased by the addition of blood.

45. **Estimation of Casein.**—Hart gives the following method of volumetric determination of casein in cows' milk: 10.5 c.c. of milk are placed in a 200 c.c. Erlenmeyer flask, 75 c.c. of distilled water, at room temperature, are added and 1 to 1.5 c.c. of a 10 per cent. solution of acetic acid. The flask is given a vigorous rotary motion. Usually 1.5 c.c. of acetic acid gives a clear and fast filtering separation, but, occasionally, with milks low in casein, a better separation is effected if a little less acetic acid is used. The separated precipitate is now filtered through a 9 to 11 cm. filter. As the casein accumulates on the filter, there is a marked retardation of the filtering process. This can again be made rapid by conducting a fine stream of cold water against the upper point of contact of filter paper and casein. This loosens the casein mass and accumulates it at the apex of the filter. This is all essential to the proper working of the process. It is absolutely necessary that all loosely combined or absorbed acetic acid be removed from the precipitate by a thorough washing and also that cold water be used in the process, in order to maintain the casein in a loose, easily soluble mass. The readiness with which the casein dissolves in the dilute alkali is largely determined by the temperature to which it has been subjected in the manipulations. A temperature not exceeding 20 C., and one that in his experience prevented the formation of large compact masses, is recommended. The particles of casein adhering to the glass of the precipitating flask need not be removed, as the bulk of the precipitate is again to be returned to the same flask. They should, however, be thoroughly

washed. The washings should continue until at least 250 to 300 c.c. of filtrate have accumulated. This insures removal of all acid. If the process has been properly conducted and the right amount of acid used in the precipitation, the filtrate will be perfectly clear.

The precipitate, together with the filter paper, is now returned to the flask in which the precipitation was made, from 75 to 80 c.c. of neutral carbon dioxid free water are added, and then a few drops of phenolphthalein and 10 c.c. of $\frac{N}{10}$ potassium hydroxid. The flask is stoppered with a rubber stopper, and vigorously shaken, either by hand or in a machine, until solution. Complete solution is easily indicated even in the presence of the filter paper by the disappearance of the white casein particles, that otherwise would settle to the bottom. After solution, the stopper is rinsed off with neutral carbon dioxid free water and immediately titrated with $\frac{N}{10}$ acid to the disappearance of the red color. It is imperative that a blank should be run parallel with the entire determination. In the author's experience it was always found that even when all ordinary precautions were taken to secure neutrality, a blank of 0.2 to 0.3 c.c. acidity was obtained. The correction for the blank—and in his laboratory it was invariably in the same direction—is made by its addition to the number of cubic centimeters of acid used in the titration. The difference between this corrected acid reading and the 10 c.c. of alkali used gives directly the percentage of casein in the milk. For example: Suppose it took 6.7 c.c. of $\frac{N}{10}$ sulphuric acid in the titration, and the blank was 0.2 c.c., then the per cent. of casein becomes 10 — 6.9, or 3.1 per cent. This method is rapid and, if properly conducted, is said to give accurate results in less than two hours.

57 Report of Twelfth International Congress on Alcoholism, held in London, July 18-24, 1909. F. L. Pleadwell, U. S. Navy.

56. **Leprosy in Guam.**—In 11 cases of leprosy, 2 of the anesthetic variety, 4 of the tuberculous variety, and 5 of the mixed variety, hydrargyrum succinimidum, gr. 1/5, was injected into the buttocks every second day for the first thirty days, then gr. 2/5 every fourth day, to date. In a few instances mild symptoms of mercuralism manifested themselves and necessitated the discontinuance of the treatment for several injections. In no case, however, did this occur until well along in the second month of the treatment. The results of nearly four months' treatment by this method are not encouraging, although in a majority of the cases some improvement of the subjective symptoms has taken place. Ten of the eleven patients state that they feel better since the treatment was begun. When asked to define the improvement they reply that they "feel better over the entire body." In 9 cases neuralgic pain was a prominent symptom. In 2 cases, 1 of the nerve and the other of the mixed type, the patients experienced entire relief from pain shortly after the first few injections; in 5 others, the attacks of pain recur less frequently and with less severity, and in the remaining 2 this symptom has not been modified. It is impossible, however, to detect any improvement in the objective symptoms. In one patient who has persistently held that he "feels better," there has been a decided loss of weight, an incipient leprous keratitis has advanced so as to destroy, entirely, the vision of the affected eye, several large ulcers of the extremities have manifested no tendency to heal, and the bacilli are far more numerous than when the treatment was instituted. In another case of mixed leprosy, a large bulla which developed on the foot during the third month of the treatment has left, as a sequel, an ulcer several square inches in area, which will eventually destroy one or more toes. A third patient has shown a decided increase in the facial lepromata, and an increase in the number of bacilli. In this and the remaining cases, aside from the improvement in the subjective symptoms, the disease has apparently pursued its normal course, unaffected by the treatment. While in some cases the existing skin lesions have healed, in most cases new lesions have appeared, so that now, after nearly four months of treatment, the individual cases show about the same number of open lesions as when treatment was begun. One patient declares that the treatment has made him worse, and he certainly has shown no improvement. Although the method has not been followed by any decided benefit, the results are not regarded as conclusive by Angeny, and it is his intention to continue the injections in the patients now under treatment and to add to the list a number of other cases.

63. **Suprapubic Operation on Pelvic Floor.**—In a case of complete relaxation, with elongation of all the interpelvic supports of the uterus, vagina and bladder, Polk performed an original operation, which, he says, is designed to aid in the correction of all degrees of prolapsus uteri, but particularly its ultra forms. The patient is placed in bed and treated for a week or ten days. Reduce the prolapse, and permit the affected viscera and surrounding structures to regain as much of the normal status as possible. After opening the abdomen, the Trendelenburg position being secured, and the pelvis (the true pelvis) cleared of all intestine, except the lower sigmoid and rectum, the uterus is firmly caught with a double tenaculum at its anterior vaginal juncture. Pulling it up and making the vagina taut, an anteroposterior incision is made reaching from the tenaculum to the bladder (which meanwhile is held against the pubis), and extending through tissue to the recognizable vaginal wall. Through this opening, which is stretched laterally, the bladder is separated from the face of the vagina as far as the trigone or even somewhat beneath it. The ureters are pushed aside, and where they turn toward the trigone are displaced upward and forward with the bladder. The next step is to unite by suture with continuous kangaroo tendon the anterolateral lines of the vagina (one on each side) from below upward, beginning as far down as possible

and ending just below the upper end of the original incision. A second line of continuous kangaroo suture is then placed, so as to draw to the median line as much fascia and covering peritoneum as can be brought in from the sides of the bladder, the vagina and the uterus. The structures in this region which must be left outside the sutures are the ureters and the uterine arteries—the arteries are in danger at the upper end of this field, the ureters at the lower. The most important loops of this suture are those employed at the lower portions of the incision—the last two need not enter the vaginal tissue, but, going down to it, pass over, and then out on the opposite side as before. Their effect will be to accentuate the line of the bladder base, and to shorten the suspensory ligament of the bladder, as well as the lateral fascial connections of the vagina and the basic lines of the broad ligaments. The uterosacral ligaments are caught up at about the junction of the inner and middle thirds, drawn in from this point and stitched with the same suture material either to the side, below or to the outside of their uterine attachment, as is most easily done. It is essential to take in as much of the slack as is needed to give them their original supporting function.

If the uterus is to be retained, the operation, as described, will be carried out with the addition, if deemed best, of shortening the round ligaments, but this is not essential. If it is a senile uterus, Polk suggests that it be thrown forward and the fundus held in the sulcus behind the bladder by a retaining suture through the round ligament at each cornua. If the uterus is removed, the operation is then executed as described as far as the completion of the suturing in front of the uterus, then this organ is dissected or cut from its lateral attachments to about the level of the internal os, stopping short of the attachment of the uterosacral ligaments. The cut surfaces of the stump are stitched together in continuation of the line of original incision; the loose ends of the severed broad and round ligaments caught up and included in this line of suturing. And finally, the uterosacral ligaments are caught up at the junction with the stump; the right is drawn over and stitched to the stump to the left, and the left is drawn to overlap the right and stitched in corresponding position to that given the left ligament. After closing the abdominal wound, further procedure can be determined by the patient's condition.

65. **Decidual Expulsion at Menstrual Period.**—A woman, 27 years of age, had given birth to a child when 24. Labor was normal. Since then she has had at her menstrual periods severe pains, simulating true labor pains, and is relieved only after the expulsion of a cast-like membrane. Before this membrane is expelled a bloody discharge begins. Her family physician attended her during three periods and each time found a complete membranous cast of the uterine cavity. The surface of this cast is finely granular. On opening the cast one sees both tubal cornua, and that the internal surface shows large and small granular elevations; the thickness of this membrane is more than 1 cm. The patient was under the authors' observation during two menstrual periods, and each time she expelled a membranous cast and suffered severe, labor-like pains. Histologic examination shows a marked decidual formation. Frankl and Scroggs believe that this is not a case of dysmenorrhea membranacea, but a true decidua; that it is a product of pregnancy, although no part of the ovum was found. Apparently, the ovum died each month in the first stages of its development. The woman admitted that she cohabited with her husband just after the menstrual period, and therefore must have been impregnated immediately. The ovum died during the first days, but the decidua remained in the uterine cavity until the time of the next menstruation. At the time of the physiologic menstrual wave the separation of the decidua from the uterine wall began in which the thrombosis of the blood sinuses perhaps helped, and it was then expelled by the uterine contractions.

66. **Unusually Large Ovarian Cyst.**—Knight's case was one of multilocular adenoma of the ovary, and some of the daughter cysts were filled with a thin pea-soup-like fluid. The fluid part of the tumor collected amounted to 96 pints. The solid part of the tumor weighed 15 pounds. The whole together weighed 111 pounds. The patient herself weighed 87 pounds when she left the hospital.

75. **Asthenia Universalis Congenita.**—In the course of his studies Stiller discovered a constitutional disease, hitherto unknown, which he has called asthenia universalis congenita. The predisposition shows itself even in the child in the atonic habitus—thin bone structure, long flat and sunken thorax, sharply sloping ribs and wide intercostal spaces. The angulus epigastricus, upper and lower chest apertures, as well as the pelvis, are narrow. The cranium outweighs the face, owing to the delicate and pointed lower jaw, the zygomatic bones and the nose being small in size also. This congenital, mostly inherited, asthenic predisposition tends to lead to a chain of disorders, which, as a rule, show themselves first after pubescence, and together with the congenital habitus form the asthenic disease. These disorders are manifold; but among them appear most often four large groups, i. e., enteroptosis, nervous dyspepsia, neurasthenia and dystrophia.

76. **Intestinal Hemorrhage in Typhoid.**—In 1,218 consecutive cases of typhoid running over eleven years in Lakeside Hospital, Cleveland, there have been 74 cases of intestinal hemorrhage, or 6.07 per cent.; 56 of them were men and 18 women. Of the hemorrhage cases in this series, 21 individuals, or 28.37 per cent., died; this is 1.72 per cent. of the entire number of cases. Of the 21 cases, 11, or 52.38 per cent., died of perforation, representing 14.8 per cent. of the hemorrhagic cases. Nine, or 12.16 per cent., died of toxemia, and one from the immediate direct effects of hemorrhage. The symptomatology of hemorrhage is often indefinite. In this series, 36, or 48.64 per cent., gave no prodromata. The symptoms recorded are: Four stools in 1 case; diarrhea in 3 cases; pain in 9 cases; sudden distention in 3 cases; fall of temperature in 13 cases; fall in blood pressure in 1 case; and delirium in 6 cases.

The chief therapeutic conception in intestinal hemorrhage is the securing and maintenance of an empty and collapsed bowel, whereby the vessels will be compressed and the conditions favoring arrest of hemorrhage will be produced. As patients rarely die as the result of the hemorrhage, and then almost always after several bleedings, one can reasonably expect that the patient will quickly recover from the results of the acute anemia, and the entire energy of the physician can be devoted, for a time at least, to stopping the bleeding. The abstinence can be continued six days after the hemorrhage ceases. A Leiter coil or cold applications to the abdomen, stimulants hypodermically, opium in small quantities for restlessness and active peristalsis and water are incidentally used as required; all bathing, except for comfort, is stopped. Lactate or chlorid of calcium is employed almost as a routine measure, although its use is not scientifically demanded unless the coagulation time is slow, which is not always the case. The older remedies, turpentine and ergot, are useless. Opium abolishes peristalsis and is an effective aid. Absolute quiet is essential.

87. **Relation of Skin Lesions to Flat-Foot.**—Billings claims that in about 80 per cent. of flat-foot cases, the skin covering the ankle and foot will present one or more conditions which seem to be closely related and always benefited, often cured, by correction of the deformity. The most common skin lesion associated with flat-foot is the callus. Excessive sweating of the feet is a troublesome skin condition frequently seen in flat-foot deformity. This condition is relieved as the foot gains in strength in its corrected position. Varicose ulcer located posterior to and above the internal maleolus is occasionally a complication of flat-foot. A soft corn between the fourth and fifth toes is almost always associated with transverse arch relaxation. Eczema between the toes, although not common, is always associated with flattened transverse arch. A troublesome fissure located between the fourth and fifth toes is often associated with a relaxed transverse arch and relieved by arch correction.

102. **Lipoma of Larynx.**—Goldstein reviews, briefly, 12 cases recorded in the literature, and cites 1 personal case in which two lipomas of large size were removed successfully under local anesthesia. A large rounded, pale, yellowish-pink mass completely filled the glottis, extending from the left lateral wall of the ventricular fossa, pushing the ventricular band upward and overlying both vocal cords. Owing to unusual size of this mass and its extreme convex surface, the left ventricular band was stretched and arched abnormally upward, so that it appeared almost in a line with the left arytenoid cartilage. The patient had complained for about a period of fifteen years of almost constant discomfort in speech and respiration, two symptoms which have become more aggravated from year to year, culminating in marked dyspnea, with change in position of the body, frequent paroxysms of coughing and marked emaciation, restless nights, nervous depression, inability to eat or to digest properly.

106. **Pemphigus of the Throat.**—In Hurd's case the pemphigus was limited entirely to the mucous membrane of the throat, an exceedingly rare condition.

120 *The Influence of the Isomers of Salicylic Acid on Metabolism. E. W. Rockwood, Iowa City, Iowa.

118. **Excretion of Magnesium.**—Mendel and Benedict find that when soluble magnesium compounds are introduced into animals by another route than the gastrointestinal tract, the greater portion of the excess injected leaves the body by way of the kidney within less than forty-eight hours. The intestinal path is of minor, if any, significance for magnesium introduced under these conditions. A considerable quantity of magnesium may be retained in the body for periods exceeding two weeks. The increased excretion of magnesium by the kidneys is accompanied by a marked rise in the urinary output of calcium. The calcium output in the feces is decreased, if any thing, at the same time. The parental introduction of magnesium sulphate in dogs and rabbits is never followed by purgation. The evidence for magnesium chlorid is not conclusive. Diuresis followed the use of both salts.

119. **Excretion of Calcium.**—The same authors find that excess of calcium chlorid may be eliminated by the kidneys and a simultaneous increased excretion through the bowel does not necessarily occur. A considerable quantity of the excess of calcium introduced may be retained for some time in the body. The increased excretion of calcium is accompanied by a rise in the urinary output of magnesium. The injections of calcium chlorid (with sodium chlorid solution) were followed by diuresis. It is suggested that the injection of either calcium or magnesium brings about the presence of an increased amount of the other metal in the blood as an antitoxic compensatory response of the organism whereby the toxic action of the injected metal is, to some extent, overcome.

120. **Influence of the Isomers of Salicylic Acid on Metabolism.**—Rockwood has experimented with metaoxybenzoic and paraoxybenzoic acids, which are isomers of salicylic acid (orthooxybenzoic acid) to determine their effect on metabolism. The experiments were made on a physician and three medical students. As is well known, orthooxybenzoic acid (salicylic acid) increases the elimination of uric acid in the urine. Rockwood concludes that this is due to an inhibition of uricolytic action rather than a stimulation of the nuclein-cleaving ferment. The meta-acids and para-acids do not affect the elimination of uric acid or of the other excretory products so far as they were determined.

126 A Nodular, Terminating in a Ring Eruption (Granuloma Annulare). G. W. Wende, Buffalo.
127 *Osteopathies of Quaternary Syphilis (Gaucher). J. M. Winfield, Brooklyn.

125. **Chronic Inflammatory Skin Diseases.**—Dühring points out that some cases of eczema, psoriasis and other diseases are *readily amenable to treatment, local or internal, or both,* while others do not respond to the same line of treatment. The cutaneous lesions in appearance and pathologic anatomy may be the same in both sets of cases, yet they behave altogether differently under the same treatment. The reason, he says, may be found in what he believes to be an observation not sufficiently recognized, namely, that while the cutaneous lesions may be the same or closely similar in many cases, the causes producing them are not only varied, but may be entirely different in nature. The internal causes, whatever these may be, producing the cutaneous disturbance should be studied more closely and treated by appropriate means. Factors giving rise to disordered states of one or another part of the economy, require to be more closely investigated than is usually done. The rôle of general medicine should be brought into action more than is customary. For some cases it is indispensable. For nearly all, if not all, the chronic or persistent or recurring cases of eczema, and for some of the cases of psoriasis, and for some other allied forms of inflammation, Dühring believes there exist specific or general etiologic factors that must be determined on the plane of general medicine, and relieved by some means or other if the patient is to be permanently cured. Local treatment alone is inadequate for most of such cases.

127. **Osteopathies of Quaternary Syphilis.**—Winfield examined 46 patients which he divided into two lots: The first 17 individuals were simply examined for the external signs of inherited syphilis, and the second 29, in addition to the external examination, were subjected to the v. Pirquet tuberculin test and the Noguchi modification of the Wassermann test for syphilis. The ages of the patients ranged from 6 months to 14 years. Nine, of the first lot of 17, had Pott's disease; 3 of these had malformed heads (Olympic); 3 had typical Hutchinson's teeth, and 1 patient had both a misshapen head and pegged teeth. The remaining 8 of the 17 were suffering from hip disease; 3 of these had dental stigmata, and 2 had malformed heads. The total out of the first 17 who presented suspicious stigmata was 12, but according to the dictum of Gaucher only 1 of the 12, the individual with dorsal Pott's disease who had two dystrophies, Hutchinson's teeth and a malformed head, could be considered syphilitic.

Ten of the second lot of 29 were suffering from diseased spine, and 11 had disease of the hip, 3 had disease of both hip and spine, 2 had suppurating sinuses of the feet and ankles, and 2 had had abscesses of the wrists and hands. All the patients were tested for tuberculosis by the cutaneous method of v. Pirquet, and all but one reacted positively, some reacting more markedly than others; the greatest reaction was obtained in a child who had all the characteristic signs of inherited syphilis, and the family history obtained from the mother left no doubt but that the child was a victim of the inherited taint; this case also gave a positive Noguchi-Wassermann reaction. Ten out of the 29 had some stigmata suggestive of syphilis; such as Hutchinson's teeth, high-arched palates, saddle-noses, overhanging foreheads and other malformations of the head; 16 had no suggestive signs and 4 left the hospital before the examination was completed. Four of the patients with external signs suggestive of inherited syphilis and 6 who were absolutely free from all stigmata, reacted positively to the Noguchi-Wassermann test, making a total of 10 positive Wassermann tests out of the 29 examined, about one-third. The most marked reaction was in patients who had two or more dystrophies, and 2 with multiple abscesses of the wrist and hand, and 1 of those with sinuses of the foot. Three with a positive Wassermann reacted feebly to the v. Pirquet test, but the remaining 7 gave a marked reaction.

One patient out of the 29 did not react to either test; this was a baby about 6 months old, which undoubtedly was suffering from syphilis, and the probable reason why it was Wassermann negative was because it had been taking antisyphilitic remedies. Six of the patients with suggestive somatic signs, and who were negative to the Noguchi-Wassermann test, had been treated for syphilis. Winfield points out that this brings up the question, Can tuberculosis and syphilis exist simultaneously in the same individual? And is it possible to get a positive Wassermann reaction in all patients with inherited syphilis, who have not been treated for the disease?

5 *Vaccine Treatment of Somewhat Unusual Interest. E. W Allen.
6 Use of the Ultramicroscope for Early Diagnosis of Syphilis H. W. Bayly.

3. **Rabies.**—The only noteworthy point in the postmortem examination of the 15 cases in this series that terminated fatally was the presence in all but one of marked increase in the cerebrospinal fluid; the relief of the intracranial tension by lumbar puncture was found in three cases to be of some value in quietening very irritable patients; six series of experiments with the fluid as a means of antemortem diagnosis produced negative results. From the few cases cited it is obviously extremely difficult to assert that any patient is suffering from incipient rabies, so alleged cures may be discounted. Treatment after the disease was definitely declared proved invariably futile.

4. **Congenital Dislocation of Hip-Joint.**—Thompson suggests that in some cases that form of dislocation of the hip-joint which occurs in young infants and children without any apparent violence, and which is usually regarded as congenital, in reality may be due to pressure exerted on the hip-joint during the adoption of the erect attitude of such a nature as to produce displacement of the head of the normal femur from a nearly normal acetabulum. The history of a well-developed girl with dislocation of the hip rarely goes back before the adoption of the erect attitude. The fact that the child is well-developed is a considerable factor in the argument in favor of the condition being static rather than congenital. The female hip-joint is weaker and acts at a greater mechanical disadvantage than the male joint. The theory of the dislocation being congenital has so far entirely failed to explain the great preponderance of cases in females. This preponderance is explained by a reference to the comparative anatomy of the joints of the two sexes. The suggestion that the condition is static more easily explains the different conditions which may be encountered in the cases of so-called congenital dislocation of the hip, which should be called static dislocation.

5. **Vaccine Treatment.**—The cases treated by Allen were the following: (1) Double systemic infection by *the Streptococcus conglomeratus* (*scarlatinæ*) and the *Staphylococcus aureus;* (2) pneumococcal septicemia, arthritis and intramuscular abscesses; (3) pyuria; (4) delayed resolution after pneumonia; (5) infection of the antrum of Highmore by the *Bacillus influenzæ* and the pneumococcus; (6) asthma and bronchitis. Careful bacteriologic examinations in over 20 cases of asthma have failed to reveal the constant presence of any one particular organism; each case presents a complex picture, most swarm with micro-organisms, and a few have shown within the casts and spirals nothing but short streptococci, and Allen feels that a variety of streptococci is of considerable importance in the production of some of the symptoms of certain cases of severe bronchial asthma. Most of the patients are still under treatment and it is difficult to forecast the ultimate results. The majority are benefiting; in two or three the bronchitis has improved greatly, but on the asthma no beneficial effect whatever has been exercised.

8. **Surface Signs in Deep-Seated Disease.**—Isaac claims that cutaneous hyperesthesia is of considerable value in the diagnosis of acute ulceration of viscera; that the neuromuscular reaction is of some value in the diagnosis of inflamed viscera; that myotatic irritability is by no means a negligible quantity; and the suggestion that there is a neuropigmentary sign in the skin of visceral disease proves that the question of superficial evidence of deep-seated disease is a far larger one than it at first seems, and offers considerable scope for both observation and research.

12. **High Specific Gravity of Urine in Healthy Women.**—On examination of 150 healthy nurses French found that a specific gravity even up to 1040 is by no means necessarily an evidence of ill-health in a woman. In the earlier cases it must be thought that there must be some error in the recording instruments; but this source of fallacy was excluded by the use of several different urinometers, each of which was tested separately; all recorded similar results for the same urine.

13. **Partial Gastrectomy for Carcinoma.**—The growth in this case was very limited, and the glandular involvement slight. This permitted removal of both with a fairly wide margin. The section of the stomach corresponded pretty well with the incision used by Mikulicz—that is, from just to the right of the cardiac orifice almost vertically downward to the greater curvature. The glands were rather soft and did not suggest involvement. An end-to-end junction after Billroth's method was used, as the cut edges could be easily brought into apposition. No trouble was experienced from leakage, the occurrence of which had led to the advocacy of other methods. The character of the growth was a colloid carcinoma. The man has been frequently seen since the operation, July 8, 1908; he has put on weight and remains free from symptoms.

September 1

43 Disorders of the Cerebral Circulation and their Clinical Manifestations. A. E. Russell.
44 *The Nature and Treatment of Surgical Shock. J. D. Malcolm.

44. **Treatment of Surgical Shock.**—Malcolm believes that the true explanation of the vascular changes of shock is that they depend on an exaggeration of the physiologic action by which stimulation of sensory nerves causes increased vascular and cardiac muscular efforts. This at once raises blood-pressure in the large arteries and lowers it in the small arteries. The lowering extends to the larger vessels in proportion to the degree of irritation. The heart is at first increased in power. Later it becomes relatively weak and its pace hastens. Its relaxation in diastole becomes so limited that it cannot take from the veins a normal quantity of blood and its output is therefore diminished; consequently the venous system becomes engorged, serum escapes from the vessels and from the body, and, if the action is sufficiently prolonged and severe, blood is almost certainly destroyed as in a fever. Thus the amount of blood in the body diminishes, and in fatal cases death is caused by a shutting-off of the blood-supply from the nervous centers. If recovery occurs, when relaxation takes place there is a marked disproportion between the diminished quantity of the blood and the vascular capacity, and therefore there is much danger from the collapse frequently observed in conditions of anemia. Therefore treatment should be directed to relaxing the vessels as shock develops and to filling them up as soon as relaxation begins. Vasoconstrictors should not be given, and attempts to dilate the vessels rapidly and forcibly should not be made. Vasodilators are indicated, but these may induce an even more dangerous condition if fluids are not at the same time supplied to fill the relaxing vessels. Complete quietude, especially in the early stages of recovery, is necessary to prevent collapse, and of course, the patient should be kept warm and recovery from the anesthetic must be attended to. The patient should not be drained of fluid by preliminary treatment, but, when time is available, this does not preclude attention to the condition of the alimentary canal, an overloaded state of which is so undesirable. All causes of weakness should be obviated as much as possible, and septic conditions should be anticipated by every means in our power.

50 Clinical Reports of the Rotunda Hospital (continued). E. H. Tweedy.

48. **Valvular Disease of the Heart.**—A woman, aged 31, had been troubled with palpitation for six years. Her feet and legs had been somewhat swollen for two months, and her abdomen had become enlarged during three weeks before admission to the hospital. She was breathless on exertion, and felt very tight and uncomfortable in the upper part of the abdomen. The liver was manifestly swollen, and with distended jugulars pointed to overfulness of the right cavities of the heart. The day after admission to the hospital the legs were no longer swollen; the distention of the abdomen seemed due to flatulence, as a resonant note was produced all over it by percussion. The urine was free from albumin and fair in quantity. A loud systolic murmur was audible over the entire cardiac region and a diastolic murmur was at first to be heard along the sternum. When 6 years old, the woman had had scarlatina. From the first the patient had a symptom not usual in heart disease, except when rheumatism is actually present. She was nearly always bathed in perspiration. The application of six leeches over the liver gave relief to her feelings of oppression and to her breathlessness. Her temperature all this time was, as a rule, subnormal; the pulse varied between 80 and 90. At the end of a week a flatulent distention of the abdomen rather suddenly disappeared. At the end of a fortnight she was allowed up pre-

paratory to going home. In the third week, however, she became mentally affected; she would not speak; she refused her food, disliked to see her husband, and at night was sleepless and noisy. The influence of drugs was curious; a hypodermic of morphin made her excited; the 1/200 of a grain of hydrobromid of hyoscin distinctly quieted her; trional in a dose of 20 grains secured sleep. All this time the sweatings continued, and in particular she often awoke out of a troubled dream bathed in perspiration. Her temperature began to rise a little at the end of the third week. For three days it did not pass 99 F., then it rose to 100, then to 101.8, and the following day to 105 F.; two days later, on the day of her death, it fell to 102 F. A few hours before her death, though she took nourishment freely, she was pulseless; no murmur could be heard.

The body was opened twenty-eight hours after death. The pericardium was injected, and the heart weighed 1 pound 5 ounces. When the great vessels were severed, a quantity of perfectly fluid blood escaped. On opening the left ventricle, its walls were found greatly thickened, but its cavity was small. When water was poured into the aorta it did not escape through the valve, and when the finger was pressed against the valvules either from the aorta or from the ventricle, it encountered a dense calcareous and spiculated mass, which appeared as if it must have entirely closed the orifice of the vessel. The left auriculoventricular orifice would admit only one finger; the two portions of the mitral valve were welded together, and the ring which they formed was thickened. The left auricle was greatly dilated, and its coats were thickened. The right side of the heart presented somewhat similar appearances. The cavity of the ventricle was enlarged and its walls were thickened; the right auriculoventricular orifice with difficulty admitted the tips of two fingers, and the valvules forming the tricuspid valve were welded together just as those forming the mitral valve had been. There was nothing like septic endocarditis; the aortic valvules, instead of being eaten away by necrotic change, had been converted into calcareous structures.

55 X-Rays in Treatment of Tuberculous Diseases. T. G. Beckett.

51. **Experimental Pathology of Diabetes.**—Knight fed animals (goats and rabbits) on food containing a very low proportion of fat, namely, bread 1 per cent., chaff 1.5 per cent., and young carrots 0.3 per cent. The animals thrived well, were killed after from three to seven days, and the amount of fat in the mucous membrane of the small intestine was estimated. In the case of goats, a quantitative estimation of the fat was made; also secretions of the intestine were examined under the microscope. In the case of the rabbits, sections were taken at different parts of the small intestine and examined for fat microscopically. A goat was fed for two days on white bread (1 per cent. fat). On the morning of the third day, the animal took a good meal of bread and water; five hours later it was chloroformed, bled by the carotid artery, and the abdomen immediately opened. The duodenum and small intestine were then removed from their mesenteric attachments. The first 6 feet of intestine contained 1.46 per cent. of fat, the middle 6 feet of intestine contained .982 per cent. of fat. Average, 1.2 per cent. of fat.

A goat fed on chaff for several days was starved for one day, then given a feed of chaff, five hours later was chloroformed, bled and the abdomen opened. The duodenum and small intestine were removed from the mesenteric attachment. First 6 feet of intestine (36 grams of mucous membrane) = .91 grams of fat—2.5 per cent. Third 6 feet of intestine (15.5 grams of mucous membrane) = .5 grams of fat—3.2 per cent. Fifth 6 feet of intestine (18.2 grams of mucous membrane) = 1.4 grams of fat—7.6 per cent. Seventh 6 feet of intestine (17.9 grams of mucous membrane) = .5 grams of fat—2.7 per cent. The mucous membrane of the intestine, therefore, averaged 4 per cent. fat.

Another goat was fed on chaff for three days, chloroformed, bled and four portions of intestine taken. First 6 feet of intestine contained 5 per cent. fat; third 6 feet contained 5.6 per cent. fat; fifth 6 feet contained 6.8 per cent. fat; seventh 6 feet contained 1.9 per cent. fat. Average 4.8 per cent. fat. If Pavy's theory that carbohydrate is converted into fat were correct, one would expect a much larger percentage of fat in the mucous membrane of the intestine, seeing that the animals were fed on a diet containing a low proportion of fat and a fair proportion of carbohydrate. In an attempt to prove or disprove the correctness of Pflüger's theory, Knight performed the following experiments: 1. Ligation of vessels between pancreas and duodenum, leaving duct intact. 2. Ligation of vessels, including duct and separation of pancreas from duodenum. 3. Extirpation of duodenum. 4. Cauterization of duodenum. Extirpation of the duodenum, and separation of the pancreas from the duodenum failed to demonstrate any glycosuria, while cauterization of the duodenum in one case only elicited a doubtful glycosuric condition. No experiments were done on the neurohepatic theory, but Knight points out that all conditions giving rise to a rise of blood pressure are liable to produce glycosuria.

54. **Antenatal Disease.**—The baby in Summon's case was born precipitately about fourteen days prematurely, and was a small child. Immediately after birth it was noticed that there was something wrong with the child's legs. There was no calcification in the femora, tibiæ or fibulæ. The feet appeared normal, also the pelvis. There was no trouble with the arms. The flat bones of the skull were deficient in calcification, but no crackling was present, the fontanelles being wide, and connected by a broad interparietal uncalcified space. The bones in the legs were so soft that they could be bent about like rolls of putty. On palpation, there was a crackling feeling, with irregularity and thickening, a feeling like that noted over subperiosteal hemorrhages. An important point noted was great tenderness of the lower limbs; the pain prohibited all voluntary movement of the legs. There was a large hemorrhage into the left side of the scrotum, and the urine was dark colored for two days after birth, producing dark stains on the linen. It was not decided that it contained blood. The legs were shorter than in a healthy child, owing to the deformity of the bones, but were otherwise normal.

The child was placed in a cardboard frame, with the legs suspended, and mercury was administered. Calcification has progressed irregularly, and great thickening and deformity may now be felt. The father states that there is no possibility of venereal disease. The mother, married young, was rather depressed during pregnancy, and had a prolonged bronchitis. She has never miscarried, and presents no evidence of scurvy.

57 *Exceptionally Large Doses of Diphtheria Antoxin in Malignant Sore Throat and Diphtheritic Paralysis. H. Méry and others.
58 *Leucemia in Infants. (La leucémie chez le nourrisson.) L. Babonneix and L. Tixier.
59 Two Cases of Fatal Diphtheritic Paralysis. J. Comby.

57. **Diphtheritic Paralysis.**—Méry states that 9 children succumbed to diphtheritic paralysis last year in his 622 cases of diphtheria; and 3 others died of the malignant sore throat without paralysis. Since then he has increased the dosage in such cases and the results have been much better. He reports 18 unusually severe cases in which the impending catastrophe was warded off by the repeated large doses of antitoxin, with 5 others in which the ordinary dosage was used, with fatal outcome. His experience confirms the value of this intensive antitoxin treatment in the unusually severe cases, keeping up the antitoxin during convalescence. While it did not prevent the development of paralysis entirely, yet the latter never appeared except in an attenuated form. Nothing suggesting

anaphylaxis and no disturbances from the antitoxin were observed in any instance. The daily dosage ranged from 40 to 60 c.c. for several days. Then, after the throat was clean, from 10 to 20 c.c. were given every day or second day. The antitoxin was given daily and the dose was increased if signs of paralysis appeared until some of the children had received over 500 c.c. of antitoxin, and all recovered. Méry affirms that there need be no fear of anaphylaxis on this dosage as that is the result of introduction of a small dose of antigen into an organism saturated with antibodies. When the antigen is supplied in large amounts, anaphylactic accidents do not occur as clinical experience has abundantly demonstrated confirming the theoretical premises. Even when the children showed signs of "serum disturbances" he did not hesitate to continue to inject more antitoxin, and the favorable outcome realized his anticipations.

58. **Leucemia in Infants.**—Babonneix and Tixier summarize from the literature 4 cases of congenital leucemia, 13 of lymphatic leucemia, including one from their own experience, 8 of myeloid and 3 of atypical leucemia, all in infants, some of whom were breast-fed. The leucemia developed between the first and second year in 13 of 21 cases; the majority were male infants. Death occurred within a few days in some cases. No treatment has been found effectual, but there is no record to date of Roentgen-ray treatment having been applied to an infant for leucemia.

62 Anatomic Conditions with Undescended Testicle. (Etude anatomique d'un cas d'ectopie testiculaire.) H. Muller.
63 *Resection of Cancerous Rectum by the Sacro-Coccygeal Route. A. Chalier.

60. **Inguinal Adenitis.**—Inflammation of the inguinal glands sometimes runs a subacute course which allows the individual to continue at work, but this retards spontaneous cure. The suppuration in these glands, Imbert states, occurs by a series of small independent foci in turn. The best treatment is by radical excision; this induces a complete cure and more rapidly than simple incision, even with curetting. His remarks apply only to simple inflammation, not of venereal or tuberculous origin. In his experience at Marseilles he has operated in this way in 21 cases, with satisfactory results, and he regards it as indicated whenever the tumor does not subside after a week in bed.

61. **Surgery of Gastric Cancer.**—Delore reviews the experiences in Poncet's service with 158 operations for gastric cancer, including 43 resections.

63. **Resection of the Cancerous Rectum.**—Chalier advocates the mode of access by resection of the sacrum and coccyx. The only means of disinfecting the rectum beforehand seems to be with superheated air at from 300 to 500 C.; a preliminary artificial anus is of great service. The upper stump after resection is invaginated in the sphincter stump, and is brought out and sutured to the skin outside of the anus; the various steps of the operation are shown in nine illustrations. It is important to retain sufficient vessels in the invaginated stump to insure against gangrene.

64 *Oxygen in Threatening Whooping Cough. (L'oxygène dans les coqueluches graves.) E. Weill and G. Mourlquand.

August 29, No. 35, pp. 349-388

65 Malte[illegible] farines de céréales et de [illegible]mbert.
66 Visibl[illegible] (Tension intermittente de [illegible] A. Mollière.

64. **Oxygen in Pertussis.**—Weill has used oxygen in treatment of threatening paroxysms in whooping-cough in thirty cases, and has found it a valuable aid in warding off bronchopneumonia and suffocation. The oxygen is given at each paroxysm; if possible, just as it begins. The cyanosis subsides and the child is relieved and keeps in good condition, with appetite, throughout. The oxygen renders the lung aseptic and thus may arrest incipient infectious processes. The oxygen must be used freely; at least 10 or 12 liters are necessary to control a paroxysm, and if there is danger of bronchopneumonia, the oxygen should be inhaled systematically every hour. It is best inhaled through a funnel during the paroxysm and can thus be given even while the child is asleep.

67 *L[illegible]bances and Ptosis of Heart [illegible]ryngés et respiratoires et
68 *Autoserotherapy in Pleurisy. (L'autosérothérapie pour activer la résorption des épanchements pleuraux.) Marcou.

67. **Respiratory Disturbances with Ptosis of Heart and Diaphragm.**—Scherb describes a case of movable heart with ptosis of the heart, diaphragm, liver and intestines, associated with phobias and obsessions involving the organs required for the patient's livelihood. The patient was a man of 53, a professional cathedral chorister, with an unusually powerful bass voice. In his singing he had evidently overstrained the respiratory organs, and about six years ago he suddenly felt intense pain in the region of the heart, and lost his voice with other symptoms of extreme ptosis of the diaphragm and heart. The sensations induced by the movability of the heart he interpreted in almost delirious fashion, resulting in an obsession of respiration and phobia of inspiration. The case shows the importance of seeking for some organic defect or displacement in every case of pathologic emotional disturbances. The importance of ptosis of the viscera in the pathogenesis of intermittent states of disturbance in the emotional sphere and will power is becoming recognized more and more. In this case, the explanation for the respiratory neurosis was found in the ptosis of the heart and diaphragm, this assumption being confirmed by the results of wearing a supporting band to hold the organs in their proper place. This put an end to the disturbing ptosis and the neurosis, and restored the chorister to the choir.

68. **Autoserotherapy for Pleural Effusion.**—Marcou makes a practice of exploratory puncture in every case of pleural effusion. If the fluid is free from pus he reinjects it directly again into the subcutaneous tissue through the same needle which is not withdrawn; the direction of the point is merely altered to bring it into the subcutaneous tissue. These autoserum injections are repeated at intervals of two or three days, the amount injected generally being from 1 to 5 c.c. He has made over 150 injections on 82 patients, and a number have been cured and under observation for three or four years. Adding those reported by Tchigaeff at St. Petersburg, by Dehio at Dorpat and others, this makes a total of 168 cases in which this treatment, first suggested by Gilbert of Geneva, has been applied to promote the absorption of pleural effusions with eminently satisfactory results, subjective and objective, immediate and remote. Marcou explains the benefit as due to the stimulation of formation of an antipleuritic substance by the injection of a product of the pleuritis. The formation of this antibody in the organism determines the rapid cure of the pleurisy. In most cases the pleural effusion is rapidly reabsorbed, but the causal affection continues its course. The most convincing cases are those with large effusions of recent date. Marcou is now encouraged to apply this same procedure in treatment of ascites. One advantage of this method is that there is much less danger of formation of adhesions and of retraction than when thoracocentesis is done. Most of his cases were in out-patients.

69 *Physiologic Research on Application of Leeches. (Recherches physiologiques sur les applications de sangsues en clinique humaine.) P. E. Weil and G. Boyé.
70 *Should Salt Food be Forbidden after Administration of Calomel? (Y a-t-il lieu de défendre les aliments salés après l'ingestion de calomel?) L. Gaucher and R. Abry

69. **Physiologic Research on Effect of Application of Leeches.**—The use of leeches is generally decried nowadays as contrary to asepsis, and wet-cupping and similar measures are supposed to answer exactly the same purpose without the drawbacks of the leeches. Weil has been the pioneer in the treatment of hemophilia with injection of normal serum, and

in the course of his research in this line he had occasion to study the effects of application of leeches. He found that the phenomena observed are different from those with wet cupping. In the first place, with the latter a certain amount of blood is drawn, but as soon as the cup is removed the flow of blood ceases. With leeches, on the other hand, the blood continues to ooze after they are removed, until from three to six ounces escape in the course of a day or so. Girardet has even reported a case in which after application of two leeches the total amount of blood lost reached thirty-seven ounces. Weil's research has explained the reason for this. It has demonstrated that the leeches seem to introduce into the organism some special substance which induces an acute, transient, local hemophilia, resembling in many respects true general hemophilia such as is induced in rabbits by intravenous injections of extract of leeches. The blood in the region is rendered incoagulable and the leech-hemorrhage persists until an amount of blood may be lost comparable to that of a considerable venesection. Wet cups, on the other hand, have no such action on the composition of the blood. When a general blood-letting is desired, leeches should be given the preference, he declares, even over venesection, unless promptly vigorous action is required, as there is no disturbance from the general or local disturbances from them, and the minute wound they form is never accompanied by infection.

70. **Calomel and Salt in Food.**—A boy of 14 with an artificial anus in the upper half of the small intestine was given calomel and the chyme was taken from the fistula and mixed in test-tubes with sodium chlorid in conditions approximating those in normal intestinal digestion. The mass was examined for the presence of bichlorid of mercury at various intervals, the aim being to settle the question as to whether the ingestion of salted foods with calomel leads to the production of corrosive sublimate in the digestive tract. The findings were constantly negative.

73 * [illegible] nd Specific Therapy. J. Bauer and Engel.

71. **Tuberculin Treatment of Tuberculosis in Children.**—Engel devotes nearly 140 pages to the detailed report of the experiences with tuberculin treatment in the children's clinic at Düsseldorf. The principle followed was first to accustom the child to a large dose and then to continue to treat him with this dosage. The children are kept in bed at first and the temperature is taken in the rectum every two hours; the injections are made between the shoulder blades. The extent of the tuberculous process determines the reaction, independent of the age of the child. Typical child tuberculosis is distinguished by a great tolerance for tuberculin. The tendency to reaction grows less when the dose which was borne without reaction is repeated several times before increasing it. When the optional maximal dose is once determined, the children are treated afterward as out-patients, the injections repeated at intervals graduated to prevent too vigorous reactions. When the child tolerates 0.01 c.c. tuberculin the reaction to the v. Pirquet test usually ceases; this test may serve as a guide for the dosage of tuberculin. His experience shows, he asserts, that it is incorrect to speak of latent tuberculosis in children; the affection may be occult and non-localizable in a child, but it is never latent. When the process has spread beyond the lymphatics the prognosis is less favorable. An acute tuberculosis in apparently healthy children is generally merely the end of an occult process, and these processes should be combated by every means. In 8 children between 3 and 8 months old the tuberculous process was apparently arrested by the tuberculin in all but one, while the medication did not interfere with the development of the children. In one case the physical findings indicated an apical process, but the recovery under tuberculin showed that the process must have been restricted to the glands. He advocates tuberculin treatment in all cases in which the lungs are not involved. There also a chance for benefit if the lung process is small with little tendency to progress, but progressive pulmonary tuberculosis contraindicates tuberculin and only discredits this method of treatment. The children thrive under the tuberculin. Fever does not necessarily exclude tuberculin treatment; small doses may even banish the fever. Fifteen curves are appended to show the dosage and progress of some of the little patients less than a year old.

73. **Immunity to Tuberculosis and Specific Treatment.**—Bauer and Engel state that the immune bodies are not found in the blood until after the children have been given comparatively large doses of tuberculin. Their experience indicates that 2 c.c. is the most favorable maximal dose. Regarding the antibody content of the blood as a favorable factor for recovery, they strive to keep it at its highest point, and found this was best accomplished by continuing with the maximal dose to support the curative efforts of Nature in conjunction with all other hygienic and dietetic factors. They are convinced that their experience with children offers a more rational basis for tuberculin treatment. Former studies of the subject have almost all dealt with tuberculous adults, while in children the local process is not so extensive. They are unable to offer direct proof of the assumed fact that the curative process is in direct relation to the antibody content in the blood. Proof of the parallelism between results in the test-tube and the process in the living organism can be obtained only by empirical observation of large numbers of cases over long periods.

83 Reform in Administration of Insane Asylums. (Zur Standesfrage der Irrenanstaltsärzte.) F. Hoppe.

77. **Dental Orthopedics.**—Warnekros reports some cases in which with the aid of dentistry methods satisfactory substitutes for large parts of the jaw were provided. In one case of bilateral luxation of the lower jaw, irreducible for sixteen years, good functional results were attained by dividing and resecting the jaw, the parts being held in place with a dental appliance until healing was complete. In another case the patient was unable to close his teeth properly and this also was remedied by resection and a celluloid dental splint appliance. The cooperation of the surgeon and dentist is especially valuable, he adds, in treating cleft palate, and cites some examples to illustrate this. He declares that in fully 75 per cent. of all cases caries is the result of defective or lacking articulation of the separate teeth involved. The loss of even a single tooth throws the chewing mechanism out of gear, imposing more work on some parts of the gum than others, while the shrinking of the gum disturbs the harmony of the projecting gum, etc., that protects the teeth, cheeks and tongue against injury. He advises prompt substitution of a lost tooth as the best means of prophylaxis against alveolar pyorrhea.

79. **Tetanus from Catgut.**—Kleinertz tabulates 33 cases, reports of which have been published in German medical literature alone. In 3 "cumol catgut" had been used, in 3 catgut prepared by the Hofmeister formalin technic, in 3 by the Saul and 2 by the Bergmann technics. The outcome is not known in a number of cases, but recovery is mentioned in only 2 and death in 17. The methods and scrupulously aseptic technic, from the first, of antitoxin production should be applied to the preparation of catgut instead of the usual haphazard [illegible]ods before the actual sterilization.

81. **Rectal Prolapse.**—In the first case a Thiersch ring was applied, and after failure at first and recurrence in a few months, a renewed application of the ring induced a permanent cure. The ring was also used in a second case, accompanied by resection by the Mikulicz technic, with satisfactory results. Piqué has reported 27 cured out of 33 patients treated with the Thiersch silver wire ring. Scraps of wire may be eliminated later, but the desired purpose is accomplished before this can occur, cicatricial tissue developing and preventing recurrence of the prolapse. Goebel remarks that the different prolapse operations are not accurately estimated to date, as too many cases are reported before sufficient time has elapsed for the definite outcome to be known.

84 *Treatment of Neuralgia by Deep Injections of Alcohol. J. Flesch. Commenced in No. 15.

84. **Deep Injections of Alcohol in Treatment of Neuralgia.**—Flesch reported last July 25 cases in which success almost invariably followed the application of deep alcohol injections. He here reviews 63 other communications on the subject, and describes the three methods in vogue. Flesch adds his commendation to those of the other writers, having found the peripheral deep injections reliable and only slightly painful, while they have the further advantage that they can be repeated as often as is necessary. Kiliani has reported 47 patients cured by peripheral or central alcohol injections in 55 thus treated, the neuralgia having resisted the other usual measures for from one to twenty years. The articles on the subject in THE JOURNAL a year or so ago are summarized with considerable detail.

97. **Treatment of Diabetes.**—In this review of his own experience *v. Noorden expatiates on the great progress realized* in adapting the diet to the individual tolerance of the patient. His experience includes about 3,000 cases of diabetes during the last fourteen years, and with careful individualization the prognosis of the disease has been materially improved. Several hundreds of his patients under observation for more than seven years have been kept free from glycosuria by changing their diet occasionally, according to the metabolic findings, and they are all now in good health, free from any complications. Most of them must still be regarded as diabetics, as any carelessness in taking too much carbohydrate would certainly bring on the glycosuria again. He is waiting for the completion of the twentieth year to publish a thorough analysis of his experiences. Of course, it is impossible to keep the diabetes under control in every case. This is due in part to the malignancy of the process affecting the pancreas, but it is especially remarkable that in the cases with a rapid course, for example, in children and in young people, it is often impossible to detect any structural changes in the pancreas. Under the age of 30, glycosuria may occur for a time and then completely subside; he has observed this after acute infections; but when the diabetes appears in the form of severe glycosuria, persisting in spite of change of diet, with considerable amounts of ketone bodies, the prognosis is almost invariably very grave. The same occurring in older persons is of much less serious import, and he has several hundreds of elderly patients who have been kept free from glycosuria for more than five years and are in excellent general health and strength on their careful and regulated diet. These cases are much more numerous than is generally supposed, while in the young this form is extremely rare. Everything depends on the systematic dietetic measures being instituted early. The whole future of the diabetic is determined by the management of the case during the early stages, except in the really malignant cases. It is difficult to persuade the diabetic of the necessity for energetic measures during this early stage, for the disease has an especially dangerous deceptive property of leaving the general health unimpaired for several years and this is a constant temptation to disregard the needed precautions. In nearly every case the glycosuria occurs transiently at first, and is explained as a harmless alimentary or nervous phenomenon, but these so-called transient glycosurias become transformed later, if neglected, into true progressive diabetes. Not until every case of glycosuria receives the attention it deserves, and not until every diabetic has his diet regulated to conform to the individual indications, will the patients share in the benefit which is possible with appropriate dietetic therapy. Not until then will it become generally recognized that the prognosis of diabetes can become far more favorable than is the case at present with the ordinary routine measures.

98. **New Methods of Sputum Research.**—Uhlenhuth calls special attention to the antiformin method. This is a mixture of a solution of potassium hydrochlorite (Javelle water) with sodium hydrate. The proportion of alkali is 7.5 per cent sodium hydrate, and on the addition of the acid 5.3 per cent. chlorin is liberated. This mixture is so powerful that it dissolves bristles, horse hairs, insects and beetles in half an hour; wool and silk are also dissolved, but cotton and wax are unchanged. Bacteria are dissolved in five minutes in a 5 per cent. solution. Neither of the ingredients has this effect alone. The action of antiformin on scraps of iron is most remarkable; they assemble to form tree-like masses. Tubercle bacilli alone are not affected and the advantages of such a fluid for examination of sputum are evident. The bacilli are cleaned at once of mucus, etc., while their staining properties are not impaired. On the other hand, this exceptional resistance of the tubercle bacillus to a chemical that almost instantly destroys and completely dissolves all other microbes, shows that there is little hope of influencing these bacilli in the body by therapeutic means; the only hope is in preventing their invasion of the body. The secret of control is in prophylaxis.

101. **Visible Peristalsis of the Stomach.**—Laache reports three cases with an illustration of one in which the intermittent stiffening and protrusion of the stomach were so violent that they could be readily watched. Such a phenomenon indicates stenosis of the pylorus, and he thinks it should be accepted as an indication for immediate gastroenterostomy. This gave good results in two of the cases and Buchholz has reported similar cases.

102. **The Stomach Mucosa in Pernicious Anemia.**—Talma reports the case of a farmer of 28 who succumbed to pernicious anemia after symptoms for eight years. The findings in the stomach indicated a reactive secondary inflammation, probably the result of poisons generated in the intestines. Talma does not regard this stomach disturbance as primary.

103. **Gastric Achylia with Anemia.**—Faber states that out of 125 cases of chronic gastric achylia 12 of the patients presented progressive pernicious anemia. Besides this group there were a number of young women with gastric achylia accompanying anemia which persisted for years uninfluenced by therapeutics. In one case iron was given for three years with only slight transient benefit. He regards this as a special form of anemia plus achylia distinguished by its protracted course and resistance to therapeutic measures. The blood findings are different from those in pernicious anemia; in the latter, the anemia seems to be due to the destruction of the blood. In the group in question the anemia was of the same type as in chlorosis and in secondary anemia from cancer, hemorrhage and the like.

104. **Universal Asthenia.**—Stiller ascribes uniformly to the "morbus asthenicus" what has hitherto been regarded separately as the "anatomic predisposition to tuberculosis," wandering kidney, gastroptosis, nervous dyspepsia, etc. All these, he declares, are merely the various manifestations of the constitutional asthenia which is not a clinical curiosity, but is encountered on every hand. Neurasthenia is an integral element of this asthenia and the latter provides the most favorable soil for certain other affections. Most striking is its genetic connection with pulmonary tuberculosis. Not every asthenic becomes tuberculous, but nearly every tuberculous patient bears not only all or most of the features of the universal asthenia, but also its most special stigma, the floating tenth rib. The dyspepsia of the tuberculous is merely the nervous dyspepsia peculiar to the asthenia. Chlorosis and gastric ulcer show a predilection for "asthenics," as also orthostatic albuminuria and a certain form of mitral stenosis which he has encountered in young women and girls. On the other hand, asthenia seems to be antagonistic to certain other affections, including typhoid, obesity, gout, chronic rheumatism, nephritis and certain heart and vascular affections. These are only rarely encountered in this congenital asthenia. The latter is the most frequent and most predominant of all constitutional affections, and represents the most universal morbid predisposition. It is not restricted to a single organ, but involves all the organs in the body. It is distinguished above all others, besides, by the fact that it has its own "habitus" and its own stigma, and these anatomic signs reveal in the child the predisposition to certain diseases, and this warning permits prophylactic constitutional preventive therapy.

107. **Arteriosclerosis.**—Huchard has investigated the causes of the arteriosclerosis in 2,680 out of 15,000 cases personally observed, and lists them according to their relative frequency and importance as gout, uricemia, the food, syphilis, tobacco poisoning, worry, mental overexertion and alcohol. He reiterates that the abuse of meat in the diet is a powerful and frequent cause of arteriosclerosis as it fills the body with poisons which have an elective action on the arteries, causing contraction, with consequent hypertension. This intoxication is early revealed by a very important symptom which he calls toxic alimentary dyspnea. It rapidly subsides when the ordinary diet is changed to milk and vegetables, which is the basis of the treatment. The mere restriction of meat in the diet puts an end to the disturbances, confirming the theory that this dyspnea, formerly called cardial or aortic dyspnea, is in reality due to the food.

109. **Flatulency.**—Besides dietetic measures and exercise, Schwartz ascribes great importance to massage of the abdomen in treatment of habitual flatulence—energetic massage with rather long sittings—attributing the benefit to the stimulation of the venous circulation. Purgatives should be used only in emergencies. Charcoal and ethereal oils sometimes benefit, although this is not the rule. With a tendency to flatulence there are generally signs of interference with the abdominal circulation, some enlargement of the liver or signs of beginning arteriosclerosis, which explain the benefit from massage of the abdomen. Cardiovascular affections also induce a tendency to flatulence from this same cause. It is also liable to occur with cirrhosis of the liver before the stage of ascites is reached. A sedentary occupation and lack of exercise are important factors in inducing sluggishness in the abdominal venous circulation with its consequent defective absorption of gases and resulting flatulency. The cardiovascular system should be carefully examined as the first step in treatment or the measures advised for the flatulency are liable to overstrain a weakened heart.

110. **Serodiagnosis of Syphilis.**—Grosser reviews the literature and his own experience with 300 cases, his conclusion being that the Wassermann reaction must not be rated too highly as a guide for treatment, but that positive findings are important in diagnosis. A persisting positive reaction, notwithstanding vigorous specific treatment, raises the question whether the infection in these cases is peculiarly resistant to mercury. The reaction is tenaciously positive in hard drinkers, and the manifestations of the syphilis in such individuals are also peculiarly rebellious to specific treatment. A positive reaction during a latent phase of syphilis generally justifies a new course of treatment and a negative reaction suggests frequent repetition of the test for a decisive conclusion. He reiterates that the nature of the reaction is still a mystery, but it is evident that it is not strictly specific.

111. **Isolated Permanent Contraction of the Vessels as a Morbid Entity.**—Pal declares that a stable contraction of the vessels with consequent hypertrophy of the heart may occur not only as a secondary phenomenon, but as an independent morbid condition. When the arterial pressure becomes high and stays high for a few hours or days, but then subsides to normal, the high tension or "pressory vascular crisis," as he calls this condition, resembles in every respect the acute high tension induced in experiments on animals by direct stimulation of the nerves or by the action of some toxic substance. Frequently recurring increased pressure may in time induce a permanently high tension. This condition of permanent high pressure may be a secondary symptom with parenchymatous nephritis, secondary contracted kidney and atherosclerosis. But in many other cases it may be the primary and basal affection, especially in certain cases suggesting atherosclerosis and in true contracted kidney. This group deserves study as a morbid entity, both from the standpoint of etiology and pathogenesis. Huchard calls this condition of high pressure and consequent hypertrophy of the heart the "stage of presclerosis," and von Basch styles it "angiosclerosis." Chronic nephritis and arteriosclerosis are generally, but not invariably, accompanied by this increased pressure so that the connection between them and the high pressure is still a problem. Pal makes a point of systematically recording the arterial pressure in every case of nephritis and comparing these records with the post-mortem findings. The maximal pressure cannot serve as a basis for estimation of the condition, only the basal pressure. There is no direct connection between the degree of pressure and the nature or intensity of the kidney process. The figures are highest with contracted kidney, but these findings are unable to differentiate a true from a secondary contracted kidney. A permanent high pressure is much rarer with arteriosclerosis than generally assumed. Very high pressure is observed at times, but this represents merely a vascular crisis which subsides sooner or later. Albuminuria may be encountered during or following it, but this may indicate merely insufficiency of the right heart, venous stasis, in consequence of the high pressure. Autopsy in a number of such cases suggesting apparently "arteriosclerotic kidney," revealed merely congestion, but no other changes in the kidney, although the arterioscle-

sis and the hypertrophy of the heart were pronounced. Such cases confirm the assumption that the kidney is not responsible for the high arterial pressure, but that some other cause must be sought. In other cases sclerosis of the coronary arteries was the only manifestation of the arteriosclerosis which had induced permanent high tension and extreme dilatation of the heart, especially of the left ventricle. In other cases slight atherosclerosis of the aorta and brain vessels was accompanied by extremely high arterial pressure, and yet the kidneys and their vessels proved to be intact, even under the microscope. In arteriosclerosis slight increased pressure has been the rule in his experience, but even pronounced low pressures have been encountered. All the data presented indicate that arteriosclerosis develops under various conditions. It may be localized or diffuse, but there is nothing to sustain the assumption that it necessarily depends on the contraction or relaxed condition of the vessels. In a case cited in detail, a woman of 42, with permanent high pressure and much hypertrophy of the heart, with signs of mitral insufficiency, developed albuminuria and headache ascribed to the arterial stasis in the brain, the whole syndrome suggesting impending acute uremia, but nothing could be discovered in the vessels at autopsy to explain the high arterial pressure which had persisted during the year and a half the patient was under observation. The kidney was intact except for stasis congestion, and the increased pressure with the consequent hypertrophy of the heart and insufficiency of the right heart must have been the result merely of contraction of the peripheral vessels. This excessive contraction may have been the result of addiction to alcohol or the effect of an adenoma found in one suprarenal. The case is instructive as showing that extremely high arterial pressure may exist in the absence of morbid changes in the kidneys and of an anatomic substratum in the vessels themselves.

117 Utilization of Pawlow Fistula into the Intestine for Pharmacologic Research Purposes. (Die permanente seitliche Darmfistel eine Methode zur Untersuchung des Schicksals und der Wirkung von Arzneimitteln im Magen-Darmkanal.) A. Bickel.

113. **Tumors of the Breast.**—Bockenheimer discusses various benign and malignant tumors, remarking that over 80 per cent. of mammary tumors are malignant according to the records to date. He reviews his experience and states that radiotherapy, fulguration and injections of certain fluids may cause the tumor to subside, but it continues its growth in the depths. Recent statistics have shown fully 30 per cent. permanently cured three years after excision. The main point is an early diagnosis and prompt excision.

115. **Free Drugs in Prophylaxis of Disease.**—Galli-Valerio emphasizes the great forward stride that would be realized in prophylaxis if all with malaria, syphilis, cretinism and typhoid could receive free an ample supply of the drugs and disinfectants required to cure and prevent infection of others.

Therapie der Gegenwart, Berlin

120 *Present Status o. [illegible] gegenwärtige S [illegible] L. Jacobsohn.
121 *The Kitchen in the Modern Sanatorium. (Die Küche in der modernen Heilanstalt.) W. Sternberg.

118. **Pericarditis with Effusion.**—Zinn pleads for more general adoption of puncture in pericarditis with effusion as a simple and reliable measure in general practice. He reviews the symptoms of pericarditis as he encountered them in over 130 cases. About 1,000 cases of acute articular rheumatism have been treated in the Bethanien Hospital at Berlin, and pericarditis was observed in 10 per cent. and endocarditis in 25 per cent. In the 100 cases of rheumatic pericarditis friction sounds were noted in 50 per cent.; in 14 there was a slight effusion besides the friction and in 35 per cent. the effusion was moderate to excessive. In pericarditis of other origin there were friction sounds or no symptoms in about two-thirds and an effusion was evident in less than one-third. In 47 cases with very much effusion the symptoms did not compel intervention in 16, but puncture was required in 25. In some of the cases the pericarditis was the first sign of the rheumatic infection and typhoid was suspected at first. All the patients in this category recovered. In case of a large effusion neighboring organs may be interfered with; in one case there was permanent recurrent paralysis, in another acute mediastinitis. Other cases show that pericarditis without effusion may occur as a primary process. Roentgen examination is sometimes useful. When puncture is indicated by threatening symptoms or by lack of any tendency to absorption of a large effusion, the best point to introduce the trocar is where the largest mass of the effusion is found and that is the fifth or sixth interspace on the left, outside of the nipple line, where there is dulness, but no friction sound nor pulsation. He makes an incision in the skin under local anesthesia, after which the puncture is made rapidly and easily and the effusion is siphoned out without aspiration. He has thus withdrawn from 80 to 300 or once even 700 c.c., but states that sometimes withdrawal of a small amount is enough to start the resorption of the rest. In case of much dilatation of the left ventricle, or adhesion of the pleural or pericardial sheets, it may be advisable to make the puncture on the right side of the sternum.

119. **The Action of the Saliva on the Secretion of Gastric Juice.**—Fricker reports a series of researches which he undertook in his own person, the results confirming the assumption that the act of chewing promotes the secretion of gastric juice, as also the arrival in the stomach of saliva, which seems to have a specific stimulating influence on the secretion of gastric juice.

120. **Brain Tumors.**—Jacobsohn gives the details of 10 cases of tumor in the brain, discussing the symptomatology in general.

121. **The Kitchen in the Modern Sanatorium.**—Sternberg discusses the arrangements by which the food can be served palatable, hot and freshly prepared, not warmed up, and he thinks that the sanatoriums can learn from hotels in this respect. He insists that fine grinding is often more important than the chemical constituents of the food. Large mortars and extremely fine sieves are important factors in the preparation of easily digestible foods. The aim should be to make a dish that melts in the mouth like fine grades of candy. The sanatorium kitchen should be provided with apparatus similar to that used in high art cooking and confectionery. His arguments to sustain these assertions were mentioned in THE JOURNAL, April 10, 1909, page 1219, and July 18, page 266.

122 *Cure of Prolapse of Rectum by Systematic Tamponing of Retrorectal Space. P. Sick.
123 *An Adjustable Drill for Extension of Bones. (Ein zerlegbarer Bohrer zur Extension am Knochen.) E. Becker.

122. **Treatment of Prolapse of the Rectum by Tamponing.**—Sick expatiates on the advantages of tamponing in treatment of prolapse of the rectum. An incision is made between the tip of the coccyx and the circular sphincter fibers, through the superficial fascia into the loose connective tissue behind the rectum. There are no vessels, muscles or nerves to be injured at this point. The rectum is then detached up to the promontory, as for resection, tamponed with a little gauze, and a strip of medicated gauze, folded four or six times is introduced. The incision 2 or 4 cm. long is closed with plaster or collodion. The tampon is removed as after a nephropexy in one or two weeks, but not until after the second or third week

should the patient be allowed to defecate seated. This technic is especially applicable for children, and he thinks it is much superior to the Ekehorn technic, which he declares is neither simple, harmless nor promising of permanent results.

123. **Drill for Extension of the Bone.**—Becker has been trying to perfect the technic of applying extension directly to the bone itself. He inserts a drill from both sides, these meet and lock in the center, while the outer ends fit into plates from which the weights are suspended. The drill is worked with an electric motor.

131 Li [illegible] the Parathyroids. (Metabolismo del [illegible] Preteso antagonismo fra tiroide e [illegible]

129. **Apyretic Malaria.**—Trincas declares that malaria should be defined as an infection which is frequently but not necessarily always accompanied by fever. There may be other phenomena taking the place of the fever, and these thermic equivalents, as he calls them, may be exceptionally serious. In the last year or so cases have been reported in which apyretic malaria induced paroxysms of kidney colic or of facial paralysis, aphasia or hemiplegia; in one case attacks of sciatic neuralgia occurred until the febrile paroxysms developed, after which the sciatica did not recur. In these apyretic cases of malaria differentiation is possible only by microscopic examination of the blood or the prompt cure under quinin.

130. **Administration of Quinin.**—Palumbo thinks that the prevailing methods of giving quinin fail to answer their purpose quite so fully as desired; the aim should be to have the blood saturated with the drug just at the time the attack is expected. He accomplishes this by giving the usual dose of 1 gm. fractioned in five doses, the last being taken just two hours before the anticipated attack. The same amount is taken on the day between the attacks, and after they have subsided he continues with smaller amounts for a few days. In 5 of his 120 cases the malaria was of the apyretic form, the attacks taking the form of trigeminal or intercostal neuralgia, recurring according to the tertian type, and all cured by two applications of quinin according to the above rule. When a large dose is given at one time about half of it is promptly eliminated, leaving only the other half to combat the parasites. A much smaller proportion is eliminated early, he says, when given in fractioned doses.

134 *Treatment of Leg Ulcers by Circular Incision Above the Ulcer. (Cura delle ulcere varicose col metodo della sezione cutanea circolare della gamba alla Mariani.) S. V. Crainz.

134. **Treatment of Leg Ulcers by Circular Incision Above.**—Crainz here reports the application of this method in 14 cases before 1908 with the ultimate outcome. In 3 cases the operation was bilateral and in 6 cases the saphenous vein was also resected. There does not seem to be any danger of thrombosis with the circular incision technic, and all of the 11 patients with the simple incision have been entirely cured to date with one exception, in which there was only improvement. There was also one failure in the 6 cases in which this technic was supplemented by resection of the vein trunk. He regards these results as a brilliant success, particularly as the ulceration in many of the cases had been of several years' standing, the lesions were extensive and deep and the patients were working people, compelled to use the leg constantly. Even in the 2 cases reported as failures, although the ulcer still persists, it has been reduced to an insignificant lesion almost entirely free from discharge. The circular incision through the skin and subcutaneous tissue encircles the leg just below the head of the peroneus.

136 Periappendiceal Inflammatory Swelling Simulating Neoplasm. (Tumore infiammatorio pseudo-neoplastico peri-appendicolare.) F. Gangitano. Commenced in No. 35.

135. **Differentiation of Pseudoascites from Rupture of Ovarian Cyst.**—Ott describes a case which emphasizes anew the importance of cooperation between the internist and the surgeon for interpretation of phenomena observed even when they are assumed to pertain exclusively to the domain of internal medicine. In a woman of 47 with supposed ascites after three years of vague lumbar pains, constipation, irregular menstruation and gradual increase in size of the abdomen, the discovery of a tumor in the right flank gave the clew to the diagnosis, especially as exploratory puncture brought a mucous rather than an ascitic fluid. At the laparotomy the abdomen was found filled with small cubes of a jelly-like substance and multiple cysts were found in the ovaries and invading the peritoneum. When the cyst ruptures insidiously and the contents escape gradually into the peritoneal cavity, as in this case, there may be no symptoms to call attention to the rupture, and the fluid obtained by puncture may not be characteristic either of a cyst or of ascites. However, if the fluid obtained by puncture contains an unusually large proportion of granulated corpuscles, a cystic origin is probable. When the rupture occurs suddenly, the symptoms generally differentiate the disturbance at once.

ENUCLEATION OF UTERINE MYOMAS; WHY AND WHEN PERFORMED[*]

E. E. MONTGOMERY, A.M., M.D.
Professor of Gynecology in Jefferson Medical College; Gynecologist to Jefferson and St. Joseph's Hospitals
PHILADELPHIA

The treatment of fibroids has ever been a mooted question. I can well remember the period when the extrusion of such growths through the long-continued administration of ergot was considered the proper plan of treatment, and the operative measures were principally confined to the reduction of the resistance to the action of the ergot. Not infrequently were seen cases in which the extrusion under this plan was so rapid that the circulation in the growth became affected and necrosis followed. Such a condition was fraught with danger whether a submucous or a subperitoneal growth.

It was not surprising that the futility of medical measures—indeed, their often disastrous effects—should have led to surgery as the means of escape from the discomforts incident to myomatous growths.

The earlier plans of treatment were necessarily confined to growths which were causing symptoms; and it is a well-known fact that the interstitial and subperitoneal rarely produce symptoms of a distressing character until sufficiently large to produce pressure or become visible through distention of the abdomen. The growths of the submucous variety, on the other hand, are very early the cause of discomfort and alarming symptoms from the profuse bleeding and the painful efforts of the uterus to expel the menacing growth.

The natural history of the extrusion of the latter growths was the origin of the ergot treatment, which was followed until the expulsion brought the growth within reach of the surgeon. Unfortunately it was but a very limited number of cases which were found amenable to such treatment, while medical measures were ineffectual or productive of additional danger to the majority.

Our present knowledge assures us that these patients suffered from weight and pressure of the tumors, from the absorption of toxins generated within them, and were endangered by necrotic and degenerative processes incident to their changing nutrition.

It is not surprising, then, that with increasing experience in operative measures within the abdomen measures should be instituted for the removal of the uterus containing these offending growths. The radical procedure was naturally chosen in view of the fact that the cases selected for operation were those in which the symptoms were so pronounced that the condition was no longer endurable. With a reduction of operative mortality, surgery has been resorted to much earlier in the history of the disease, and some have accepted the dictum that the pickled fibroid is the only fibroid to leave unmolested. The advocates of early operation are confronted with the recognition of the fact that early operation must necessarily result in the arrest of all hope of conception in a large number of comparatively young women, for fibroid growths are recognized as occurring in women between 25 and 40 years of age.

It is true that the presence of fibroids increases the tendency to sterility, but the large number of cases of the coexistence of pregnancy and fibromas demonstrates that they do not make sterility absolute.

The study of the specimens removed, showing the enveloping capsule and the ease with which the tumors could be peeled out, make the consideration of the removal of the growths and the preservation of a functionating uterus seem justifiable. The aim of any capital operative procedure is to save life, but the preservation of the function should be considered as next in importance, especially when the function preserved has to do with the propagation of the species.

Not infrequently a woman will place but little value on her ability to bear children—may, indeed, endeavor to avoid the responsibilities of the marital relation—but when she realizes that some operative procedure is followed by premature menopause she awakens to a realization of the fact that the function lost was one she prized beyond every other, and is so disturbed by her loss that the mental faculties become unbalanced.

The premature menopause frequently produces marked nervous and vasomotor disturbances, which destroy all comfort and pleasure in life. The combination of these symptoms with the mental phenomena induced by the knowledge of inability to conceive leads to mental derangement. As it is beyond our possibility to determine in advance the influence such measures will exert in any individual case, it seems the better procedure, whenever possible, to preserve the uterus and remove the growths.

An advantage of this procedure which is not always apparent to the patient in whom there is a recurrence is that, should the worst come and the growths recur, we can then if necessary do a second operation which will not, in the majority of cases, be required until years after the first. On the contrary, should the removal of the pelvic structures as a primary procedure be productive of deleterious effect, there is no plan by which we can replace the organs, and in many instances there is but little reason to hope for improvement.

I will not attempt to occupy the attention of the Section with the details of enucleation further than by remarking that the operation may be either vaginal or abdominal. The former should be employed only when the growths are limited to those which encroach on the uterine cavity or are confined to the lower portion of the uterus, making them readily accessible through a roomy vagina.

---

[*] Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In either the vaginal or abdominal procedure, the aim should be to do as little injury to the organ as possible; consequently the number of incisions into the uterus should be limited. The vascular supply to the growths occurs through the vessels of the capsule; consequently the hemorrhage is at times quite considerable and requires the employment of measures for its control. Some operators advocate the application of a rubber ligature about the cervix during the process of enucleation, but I have never found this necessary, as the bleeding can be controlled by pressure forceps direct to the bleeding vessels. Large vessels or sinuses should be ligated by passing a needle armed with a catgut ligature beneath the vessel. The wound or wounds in the uterus should be closed with interrupted catgut sutures and then with a second or superimposed row of sutures to bring the peritoneum in contact over the line of the wound. I formerly closed such wounds with several rows of continued catgut suture, but not infrequently the loose capsular connective tissue is of such low vitality that occasionally all the tissue inclosed in the line of suture will become so devitalized that it will slough out.

In reviewing my own work done to retain the uterus, I find about thirty-seven cases in which fibroids have been enucleated through an abdominal incision, and five cases in which the operation has been accomplished *per vaginam*. A large number of cases of myomectomy either through the vagina or by abdominal incision are not included, but only those in which the growths have been enucleated. In five of the abdominal cases, the operation was performed during gestation, and in all the patient continued to carry the offspring until the completion of pregnancy. In none of the cases has there been any trouble during labor. In several of the patients the convalescence has been stormy or prolonged, and in two death resulted. In one patient, a single woman, aged 33, thirteen growths were enucleated. The wounds were closed with several layers of continuous chromicized catgut suture, and finally the sutured surface secured to the lower angle of the abdominal wound. Her convalescence was disturbed. The abdominal wound became infected, and finally there was discharged through it a slough which contained the entire suture material employed in the fundus of the uterus. After a prolonged period the woman recovered, subsequently was married and gave birth in successive labors to two children. Her first labor was unattended by anything abnormal. Following the completion of the second, she went into collapse and died with what was supposed to be a rupture of the uterus and internal hemorrhage.

The growths have varied from one to twenty in number, and from the size of a pea to that of a child's head. The smaller, of course, were multiple. In eight cases the disease of the uterus was complicated by disease of the ovaries or tubes, requiring operation on one or both tubes. In one a hemorrhage occurred which required a vaginal incision some ten days later to evacuate the accumulation. In three cases it has been necessary to reoperate, and in one of them a second time. The latter operation was not for fibroids, however, but for appendicitis, and the opportunity was taken to overcome a ventral hernia. In one of these patients reoperated on, from whom two fibroids were enucleated at the first operation and no vestige of others recognized, at the second operation, five years later, twenty were enucleated and both ovaries removed for diseased conditions. One patient, from whom twenty growths, large and small, were removed eight years ago, now has a large collection, but as the menopause has occurred and they are not producing symptoms I have advised delay.

My analysis of my own cases and the study of the literature has caused me to regard the removal of fibroid growths by enucleation as indicated in the following conditions:

1. When the growths are few in number and the structure of the uterus is but little involved. Of course, the fibroids may be numerous but situated so near the surface as to permit their removal with but little injury to the general structure, but the large number indicates a tendency to fibroid degeneration which presages early redevelopment. Where a number of growths of considerable size are present, the structure of the uterus is so spread out and will be so injured as to render an attempt to save the organ attended with danger during the subsequent convalescence and an element of danger in the event of pregnancy and labor.

2. When the growths are readily accessible through the vagina or cervical canal. A growth within the uterus, either a sessile submucous or an interstitial, is readily attacked. Not infrequently, the canal may be partially dilated and the dilatation can be completed by the introduction of tents, or the cervix may be split bilaterally until the tumor is exposed or rendered accessible. The enucleation completed, the cavity may be packed with gauze and the split cervix closed much as is done in an ordinary trachelorrhaphy. The vaginal operations are attended with less constitutional disturbances than in the removal by an abdominal incision.

3. When the woman, whether unmarried or married, is under forty years of age, and particularly when she is childless or has but one or two children. The removal of the growths at an earlier period can not be considered as rendering certain the escape of the patient from recurrence, for one of my patients who had two fibroids enucleated when she was 33 years old five years later had twenty removed. The age of forty, however, is one at which the individual suffering from such growths begins to undergo retrogressive degenerations and when the patient has not previously been fertile pregnancy is much less likely to occur.

4. When the tubes and ovaries are free from complicating conditions. The existence of tubal or ovarian disease of sufficient gravity (as hydrosalpinx, or pyosalpinx, or ovarian hematoma), to render the probability of conception remote or to necessitate the removal of tubes and ovaries to insure restoration of health, should also be an indication for the removal of the fibromyomatous uterus. While it is true that in the majority of cases the tumors decrease and become quiescent after the menopause, yet they sufficiently often undergo necrosis and other degenerative changes to justify the removal of the uterus.

I have endeavored to indicate the conditions under which the enucleation of myomatous growths may be considered advisable, but it would seem even more important to enumerate some of the conditions in which experience has demonstrated that such a procedure would be inadvisable or even dangerous. On general principles, I would condemn the operation (1) when the woman affected has reached the age of forty, as with the changing conditions incident to the climacteric, the tendency to degenerative processes is increased. The woman who reaches this period unmarried or childless is unlikely to be fertile and the tendency to sterility will be augmented by the disease and the operative procedure required for its relief. I consider it inadvisable (2) when the uterus is spread out by the growth or growths to such a degree that the reconstruction of a functionating uterus will not be feasible, and (3) when the tumors are so distributed in the structure of the uterus that the circulation will be greatly affected in the necessary suturing to replace the disordered structures.

The danger to the patient is so great in both of the classes indicated in 2 and 3 as to render attempts to preserve the organ not only inadvisable but unjustifiable. The patient is endangered during the convalescence from necrosis and infection of the structures of low vitality, from accumulation of blood in the torn tissues, and in some cases from extensive sloughing of the devitalized structures. Should she survive the operative danger and subsequently become pregnant, she is still in danger from uterine inertia or from rupture, as evidently occurred in one of my cases.

Enucleation of growths may occasionally be of service in promoting the procedure of removal of the uterus. Its employment reduces the bulk of the mass, permitting more ready access to the tissues of the pelvis. I have made use of it, as have others in many instances, to lessen the bulk and afford more ready access to the deeper structures of the pelvis. But two cases recur to me in which it was of especial advantage. The first was that of a woman who had been subjected to an abdominal incision and the wound closed because the conditions seemed too formidable to justify further procedure. When I opened the abdomen the pelvis was so packed with the growths that the vessels were inaccessible in any direction; but the enucleation of a large number of growths rendered the shell containing the blood-vessels readily accessible and the operation easily completed.

Recently I operated on a woman past the climacteric who had carried a large tumor over eighteen years. Of late she had been suffering from abdominal pain and elevated temperature. When the tumor was exposed it was found firmly fixed, filling the large pelvis, and with the intestines so adherent to its posterior surface as apparently to defy dissection. As progress seemed unfavorable in front, behind or on either side I determined to bisect the mass. Incision disclosed that the uterine wall, nearly an inch in thickness, covered a large necrotic fibroid. This was turned out, the inner surface of the uterus curetted, the bleeding vessels ligated and the organ closed without disturbing the adherent intestines. The convalescence was unusually rapid and satisfactory.

1703 Walnut Street.

ABSTRACT OF DISCUSSION

Dr. H. J. Boldt, New York City: I desire to endorse Dr. Montgomery's position as to the limited indication for myomectomy; in other words, myomectomy should not be done when the uterine structure has been greatly encroached on by a large number of myomatous nodules within the organ. An inflammatory condition of the ovaries and tubes does not mean that the ovaries should be removed. With malignant change taking place in the neoplasm, particularly in patients over 40 years of age, I believe entire extirpation of the uterus is indicated rather than a supravaginal extirpation of the uterus. In patients below or about that period it is more desirable to retain the cervix and the adnexa for obvious reasons, unless there is a question of malignancy. In appendicular inflammation, the inflammation is not necessarily present only in those cases in which it is seen macroscopically; in the majority of cases in which the appendix has been removed it has been demonstrated microscopically that there was present an inflammatory condition of the appendix.

Dr. Howard A. Kelly, Baltimore: I agree with Dr. Montgomery that myomectomy is the operation *par excellence.* When a patient comes to us our first thought is: Can I take out these tumors? Not: Can I take out the uterus? And leaving out the age limit in young women, in the absence of complications I always try to do a myomectomy. But a myomectomy is undoubtedly more dangerous than hysterectomy. I have had over 200 cases of myomectomy and the percentage of mortality is large. The operation is dangerous on account of the possibility of serious secondary hemorrhage and of infection, particularly of the former.

I have only perhaps in the last fifty or sixty cases operated by methods in which I feel secure against this accident. They consist in limiting myself to the cases in which there are not so many tumors. I expose the uterus, tie with a little gauze strip, and bisect the tumor. It is of great advantage to use a serrated instrument. A large vessel supplying the tumor should be clamped as an ordinary bleeding vessel. If after having taken off the pressure and having clamped these vessels, there is still free hemorrhage, they should be tied very carefully as described by Dr. Montgomery. The method of suture is important. The vessels should be caught and sewn together with a strong continuous catgut suture. I sometimes make the figure-of-eight suture which binds the sutures between where they tie and loop. It is the best suture I know of in loose flaccid tissue to stop hemorrhage. Most important of all and that which has helped me with my myomectomies and the only thing by which I can feel safe is to close up the wound with a little bit of a drain. It is not enough to interfere with the prompt healing and when I pull it out after two or three days I always know whether there has been hemorrhage. There is always a surprising amount of leakage; if there is too much the wound is opened up. The little telltale drain has been invaluable in enabling me to feel comfortable about the patient. It can be removed on about the third day.

Dr. E. E. Montgomery, Philadelphia: It is not in the simple case, the case in which the fibroid is small and the operation slight, that death is likely to take place. I would not for a moment wish to be understood as advocating operation in every case in which fibroid tumor is recognized; but I do say that such cases should be kept carefully under observation; that the growth of the tumor should indicate early operation, principally for the purpose of trying to save the patient's functions and her power of propagation. When the tumor has gone beyond this early stage and shows extensive development in the uterus we should resort to operation and safeguard the life of the patient.

Objections to External Splints in Fractures.—H. E. Pearse, in *Kansas City Medical Index-Lancet*, gives the following objections to external splints: 1. It is impossible to see the ends of bone, hence impossible to secure accurate apposition of ends. 2. Breaks are never so transverse as not to slip sidewise on occasion. 3. Portions of fascia and muscle will become misplaced and engage between the ends of bone. 4. The hemorrhage from broken bones does not stop until the parts are packed with a blood clot that must be absorbed and whose presence increases the stiffness and uselessness of the mended member. 5. External splints applied over the parts, separated from the actual broken bone by the muscle, fat and skin, cannot hold the parts in more than indifferent position and then only by exerting undue pressure on the soft parts. 6. Too often one fragment is too short to afford proper bearing for the splint and thus maintain the axis of the bone in proper position. 7. Every factor of the external splint process used to maintain apposition—splints, bandages, pressure, extension and rest—all these tell against nutrition. 8. Early motion, which is the panacea for stiffness and loss of function, must be sacrificed to the need for bony apposition.

INSECT CARRIERS OF TYPHOID FEVER *

W. FOREST DUTTON, M.D.
PITTSBURG, PA.

The events brought about by the Spanish-American war marked the beginning of the greatest epoch in the history of preventive medicine in America. The arrest of the growth and propagation of certain mosquitoes—anopheles, culex, and stegomyia—has blazed the way for the greatest achievements of modern times.

FLIES

Insect carriers of disease have not, until a comparatively recent date, received any impressive attention from medical observers. The mosquito was, perhaps, the first insect to receive due attention. Its importance as a host in malaria, yellow fever, and other diseases has been thoroughly established.

The common house-fly (*Musca domestica*), since time immemorial, has been a common nuisance of all countries, civilized and uncivilized. My first observations of the house-fly as a carrier of disease were made in army camps during the Spanish-American war. It is well known that the army camps of this war were veritable hotbeds of typhoid fever. Some outbreaks could be readily traced to the water-supply; in other camps, where the water was free from contamination, the cause of the spread of typhoid was at that time unknown. Other observers (Veeder, Craig, Austen, Stalham, Oldham) have connected the fly with the transmission of typhoid in army camps.

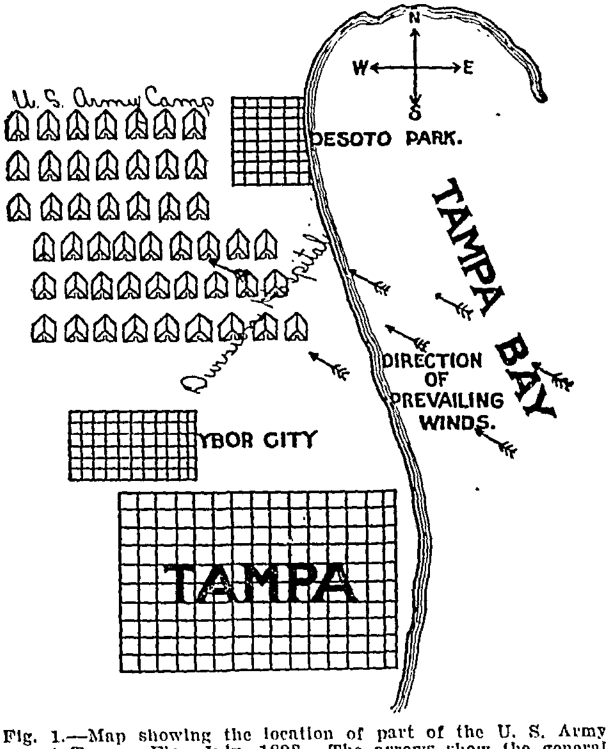

Fig. 1.—Map showing the location of part of the U. S. Army camp at Tampa, Fla., July, 1898. The arrows show the general direction of the prevailing wind and indicate how infected flies were carried from hospital, latrines, etc., to other parts of the camp.

While stationed at Tampa, Fla., in the early summer of 1898, I observed that the larger outbreaks of typhoid took place and spread in the direction of the prevailing wind. I did not fathom this peculiar phenomenon until Sergeant Brady was stricken with typhoid fever at Fernandina, Fla., some months later. He mentioned to me that the lime used about the latrines and garbage dumps was carried by flies to the food which we were using. After investigation, I found that the flies did not only carry lime, infectious matter, and other foreign material, but that they traveled in the direction of the prevailing wind.

Dr. Thomas S. Anderson, of Pittsburg, has recently confirmed and observed the factor of the prevailing wind in the spread of typhoid. In a symposium on typhoid fever before the Allegheny County Medical Society, Pittsburg, Pa., held April 20, 1909, Dr. J. F. Edwards, superintendent of the Bureau of Health, said that with the many open box privy vaults in the densely populated parts of the city the possibility of flies as carriers of disease might be a factor, but that his department had no knowledge that such was the case. Pittsburg until recently had one of the largest typhoid mortality rates of any municipality in the world. Thus, one notes how easy it is to overlook some of the most important factors in the transmission of typhoid.

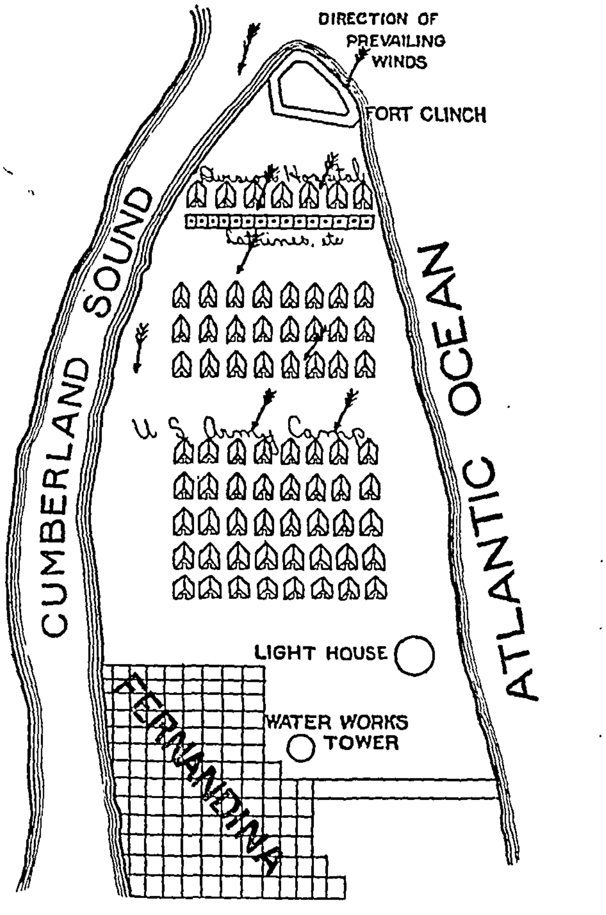

Fig. 2.—Map showing the location of the U. S. Army camp at Fernandina, Fla., 1898. The arrows show the directions of the prevailing winds and indicate the direction flies were carried from infected sources to different parts of the camp.

According to the investigations of Dr. Hamer, of the London County Council, the most productive of all factors in the fly genesis are accumulations of horse manure, but collections of dust and other refuse act as breeding-grounds. He states further that children, dirty walls and ceilings, particles of food on the floor and in sinks, are influential in attracting flies.

It has been shown that flies may carry typhoid fever germs in a living condition for over two weeks. Experiments have shown that typhoid bacilli may pass through the intestinal tract of the fly and remain alive. The germ is not so readily carried in the body of the fly as on its hairy feet. The urinals, linen, and even the mouth and rectum, as seen in many army camps, are places most likely for the fly to frequent, and thus pick up germs and become a most potent medium for the dissemination of the disease.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The true or common house-fly (*Musca domestica*) commonly lays its eggs on horse manure (its favorite food), cow manure, human excrement, and decaying animal and vegetable material. Howard has found that in midsummer each female lays 120 eggs, which hatch in eight hours, the larval period lasting five days, making the total time for the development of the generation ten days. This was at the end of June in Washington, D. C. The periods of development vary with the climate, season, and food. In the climate of Washington there is ample time for the development of twelve generations every summer (Howard).

Pomace-flies, or little fruit-flies, are commonly seen about decaying fruit and other decaying vegetation (Howard). The most abundant and widespread species is *Drosophila ampelophila,* the vine-loving pomace-fly (Kellogg). These flies are frequently found feeding on table fruits such as pears, peaches, plums, grapes, and apples. Fruit furnishes both food and a place for oviposition for these insects. Kellogg has observed: "The larvæ or maggots hatch in three to five days, live in the fruit four days, and lie in the pupal stage three to five days, so that the life cycle is gone through in less than two weeks."

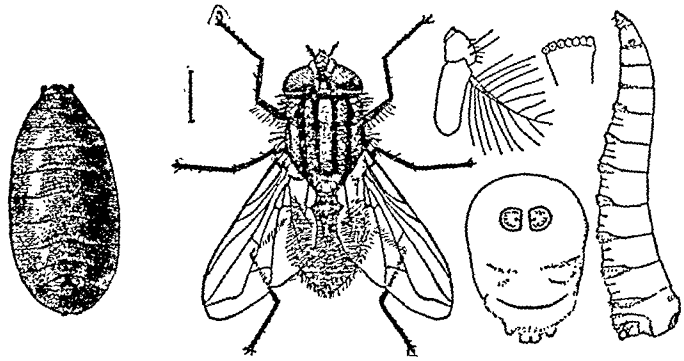

Fig. 3.—Common house fly (*Musca domestica*) : Puparium at left; adult next; larva and enlarged parts at right. All enlarged. From circular 71 (by L. O. Howard), Bureau of Entomology, U. S. Department of Agriculture.

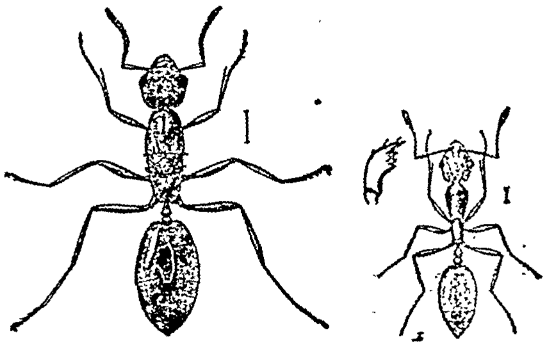

Fig. 4.—The red ant (*Monomorium pharaonis*) : A, female; b, worker. Enlarged. From circular 34 (by Riley), Bureau of Entomology, U. S. Department of Agriculture.

It is difficult to rate the importance of the pomace-fly as a carrier of disease. Howard has recently shown that these flies are attracted to dangerously foul substances, and that they may be responsible for the spread of certain diseases. Their method of dissemination of disease is much the same as that of the house-fly, with this exception that pomace-flies often breed in the food used by man, and their significance as carriers of typhoid bacilli can not be overestimated. In Pittsburg, September, 1908, I secured cultures from pomace-flies found in a garbage-can in which excreta had been thrown, and within one hundred feet of a restaurant where hundreds of people dined daily.

HOUSE-ANTS

The most important species of ants found in houses is the little red ant (*Monomorium pharaonis L.*), the little black ant (*Mouomorium minntum Mayr*), and the pavement ant, of the Atlantic seaboard (*Tetramorium cæspitum L.*).

Perhaps the little red ant is the most thoroughly domesticated. It passes its entire existence in or about houses, having its nest in the walls or beneath the flooring, or in other places favorable to rapid ingress or egress near articles of food.

The habits and life histories of these several species of ants are much the same. The specimens usually seen in houses are all workers. The colony itself contains the larger wingless females, and at the proper season the winged males and females. During the greater part of the year the colony consists mostly of workers with one or more perfect wingless females.

In squalid homes, where the garbage-pail is used for the deposit of excreta, etc., it can be readily understood how these insects may become carriers of typhoid infection.

COCKROACHES

The cockroach is among the commonest and most offensive of insects which frequent human habitations (Marlatt). The American roach (*Periplaneta Americana*) is the commonest of domestic species found in America. The house roach is particularly abundant in pantries, kitchens, store-rooms, and especially in the neighborhood of well-heated apartments. It conceals itself during the day behind baseboards, refrigerators, boxes, furniture, in damp or moist cracks about sinks, and wherever protection from light is afforded. Unless routed out, or suddenly uncovered from their hiding-places, roaches are rarely seen. If discovered, they make off rapidly for other secure hiding-places. Domestic roaches congregate in large numbers at night and feed on almost any kind of food, dead animal matter, cereal products, leather, cloth, and such other materials as may suit their fancy for food or destruction. It is said that roaches are occasionally cannibalistic. They seem to be natural enemies of the bedbug, but as they do not usually frequent the places inhabitated by the bedbug they are not valuable as exterminators of that insect. Roaches travel from place to place, wherever their instinct may lead, to fertile fields for foraging.

Marlatt says:

> The roach, in its different stages from egg to adult, shows comparatively little variation in appearance or habits. The eggs, instead of being deported separately, as with most insects, are brought together within the abdomen of the mother into a hard, horny pod or capsule which often nearly fills the body of the parent. *On hatching, it is said,* the young are often kept together by the parent and brooded over and cared for; at least, a colony of young will usually be found associated with one or two older individuals. The common American roach (*Pariplancta americana*) has been carried from egg to the adult state in our insectary. Young hatching July 11

from an egg-case received from Eagle Pass, Texas, reached the adult stage between March 14 and June 12 of the following year, indicating a period of twelve months for development. The rate of growth undoubtedly depends very largely on food and temperature.

The omnivorous habits of the roach make it a prolific source and a ready carrier of disease. Engelmann has observed the relation of the cockroach to the conveyance of typhoid infection. It may carry disease from the source of infection on its body and limbs, or, by excreta, to drinking or other vessels used about the household, or even into the food.

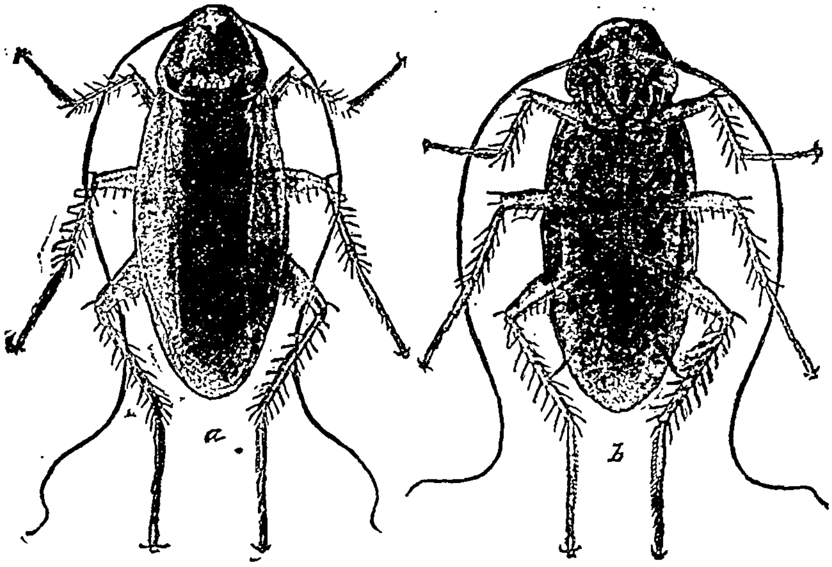

Fig. 5.—The American roach (*Periplaneta americana*) : A, view from above ; b, from beneath. Both enlarged one-third. From circular 51 (C. L. Marlatt), Bureau of Entomology, U. S. Department of Agriculture.

HOUSE-FLEAS

The human flea (*Pulex irritans L.*) and the dog and cat flea (*Ctenocephalus canis, Curtis*) are among the common nuisances found in houses in this country. Howard maintains that the flea most likely to be found in dwellings in this country is the cosmopolitan flea of the dog and cat. My observations, however, do not tend to confirm this, except in homes where these animals are kept. The human flea (*Pulex irritans*) is the prevailing flea of our country, and more especially in stock-raising districts. In small villages, where the homes are well-shaded and with a tendency to dampness, human fleas may be found in abundance. I have known an entire village to be infested with fleas after a drove of hogs and cattle had been driven through it. Homes that are damp during the summer are most liable to be infested with fleas.

The eggs of the *Ctenocephalus canis* are deposited among the hairs of dogs, cats, and numerous other animals. They may be deposited where animal material is free. There they develop and live until full grown. In warm, damp weather a generation may develop in a fortnight.

The flea, as a factor in the dissemination of plague and some other diseases, has been so fully established that it does not call for further comment here. The flea as a carrier of typhoid has not been so thoroughly brought out. From some 500 human fleas which were allowed to suck the blood of typhoid patients I have secured twenty cultures. Typhoid cultures were secured from 5 out of 650 of the dog and cat fleas. The extreme difficulty in securing the fleas, keeping them in captivity, and placing them in an artificial environment after possible injury, gives, I believe, a good reason for the small percentage of cultures. I am fully convinced, as were my confrères, that two of the cases which came under my service were inoculated by the house-flea.

BEDBUGS

The bedbug (*Cimex lectularius L.*) is the most loathsome insect infesting the habitations of man. It is commonly found in the homes of the squalid, yet it may be found in the palaces of kings. It is found in the cracks and crevices of old houses, in old mattresses, bedsteads, and more especially when these are approximate to human beings. It is nocturnal in its habits and inactive in cold weather. The food of the bedbug is normally human blood, yet it may subsist for a time on other substances. The eggs of the bedbug are laid in such places as are used by them for concealment. They are laid in clusters, each cluster containing six to fifty eggs. The period of growth, from the egg to the adult, varies greatly with temperature and food supply (Howard). Under ordinary conditions eight or ten weeks is necessary for rearing a generation of bedbugs.

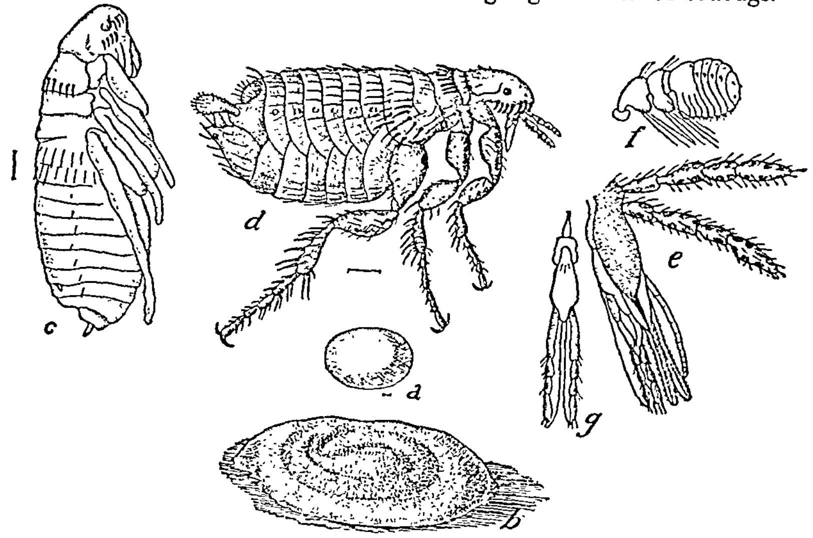

Fig. 6.—Cat and dog flea (*Ctenocephalus canis*) : A, egg, b, larva in cocoon ; c, pupa ; d, adult ; e, mouth-parts of same from side ; f, antenna ; g, labium from below ; b, c, d, much enlarged ; a, e, f, g, more enlarged. From circular 108 (by L. O. Howard), Bureau of Entomology, U. S. Department of Agriculture.

The bedbug has been found by observers to be a factor in the transmission of various diseases, as tuberculosis and relapsing fever. I believe that my investigations, covering a period of three years, have a prior claim over that of others in respect to the transmission of typhoid bacilli by the bedbug. I had observed among Poles, Italians, and Russians, in filthy quarters, where the beds had been used by typhoid patients, that succeeding occupants were stricken with typhoid. I had noted that after having been bitten with bedbugs, in from eight to fifteen days they were attacked with typhoid.

This disease-carrying factor was suggested to an Italian tenant of one of a number of typhoid-infected houses, with the advice that the beds be destroyed by fire and the house fumigated. The advice was refused. To test the case, the man offered himself for experiment. I collected some bedbugs, starved them for several days, then placed them on the abdomen of his 8-year-old daughter, who had typhoid, incarcerating them under a square piece of a fleece-lined undershirt, fastened at the edges with zinc oxid adhesive plaster. In six hours the bugs, satiated with blood, were imprisoned between soiled pieces of canvas and allowed to remain twenty-four hours. They were then transferred to the abdomen of the father, imprisoned in the same manner as on the child, and allowed to remain twelve hours. It was noted that only about one-third of the bugs had bitten the subject. After removal, the bugs were crushed between glass slides and cultures made. These cultures showed the Eberth bacilli. Unfortunately, a few of the bugs escaped and fed on the blood of an 11-year-old boy, with whom the subject was sleeping. The father developed typhoid of the most virulent type in fourteen days and the boy in twelve days. The vitality of the *Bacillus typhosus* in the bedbug persists for several weeks, without any apparent lessening in virulency. In the case of the boy referred to above, the virulency was greatly increased.

MOSQUITOES

There are some 300 different mosquito species in the world, representing two dozen distinct genera. In North America, there are sixty species, representing ten genera. In the family Culicidæ are included two distinct types of mosquito, one with mouth-parts forming a long, slender, sucking proboscis, provided with sharp, needle-like stylets for piercing, the other with mouth-parts short and better adapted for lapping or supping liquids (Kellog). Two genera have a mouth of the latter type; all the others are piercers and blood-suckers. The females normally feed on plants, but when opportunity offers they feed on the blood of warm-blooded animals. Three genera of the piercing type are of special importance and interest to the medical profession, because of their relation to the development, incubation and dissemination of certain diseases of man and beast. These three genera are the *Culex, anopheles* and *Stegomyia* and, according to Kellogg, may be distinguished as follows:

Palpi (the mouth-feelers projecting by the side of the proboscis) long in both male and female, about as long as the proboscis: *Anopheles*. Palpi as long as proboscis in male, but only one-third as long in female. Scales on the head narrow and curved: *Culex*. Scales on the head flat and broad: *Stegomyia*.

Stegomyia and *Culex* are the breeders and disseminators of yellow fever and filariasis, and to the anopheles is given the responsibility of the breeding of malaria. I have been able to make cultures, in two cases, from mosquitoes (anopheles) after they had been satiated with the blood of a typhoid patient. Although this is not enough clinical evidence to be conclusive, it marks a starting-point for further investigations. I believe, however, that I am not alone when I say that mosquitoes may be active disseminators of many other diseases.

It is generally conceded that the larvæ of mosquitoes are aquatic, yet they are air-breathers. They are rapid breeders and may pass through several generations in the course of a year. The duration of a single generation may be twelve days. As adults, they hibernate and may be found during winter months in houses, barns, cellars, cisterns, culverts, etc. Mosquitoes do not fly far, but may be carried by light continued winds considerable distance from their breeding-places. An important factor to be noted in the spread of yellow-fever epidemics, as well as other insect-carried diseases, is the direction of the prevailing wind.

REMEDIES

Hydrocyanic-acid gas is one of the most effective remedies against household insects. The cyanid and gas is a deadly poison, and great care should be used when a house is fumigated. Some old remedies are insect powder (as pyrethrum), benzine, kerosene, corrosive sublimate, oil of turpentine, fumigation with sulphur, bisulphid of carbon, and traps. Many insects have natural enemies; as the roach and red ant against the bedbug, the ichneumon fly and tree-frog against the roach. A careful screening of windows and doors during the summer months, the use of sticky fly-paper and the elimination of breeding- and feeding-places will soon abate the fly nuisance. The means and methods of attack on the mosquito have been clearly delineated in recent literature by Gorgas, Guiteras, White and others. I will say in passing that by draining swamps, ponds and pools, the introduction of petroleum and other substances to kill the larvæ, the dissemination of dragon flies, and the screening of houses, cisterns, barrels, etc., leaves little for the pest to thrive on.

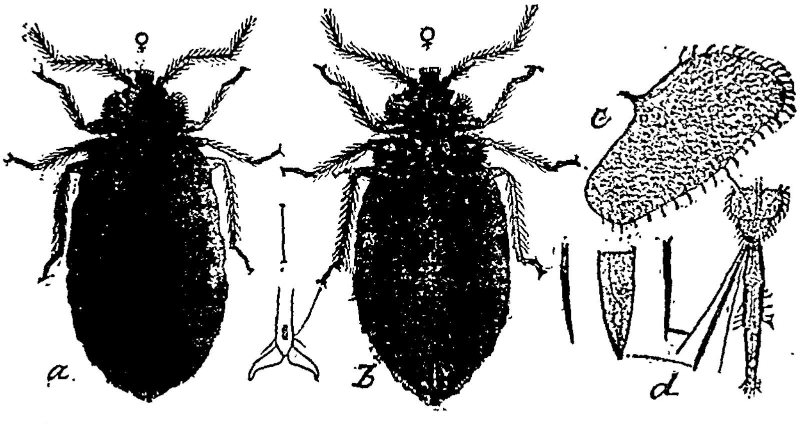

Fig. 7.—Bedbug (*Cimex lectularius*): A, adult female, gorged with blood; b, same from below; c, rudimentary wind-pad; d, mouth-parts; a, b, much enlarged; c, d, highly magnified. From Circular 47 (by C. L. Marlatt), Bureau of Entomology, U. S. Department of Agriculture.

The stools and urine of typhoid patients must be disinfected with chlorinated lime, or by cremation the moment voided. Especial attention should be given to the antiseptic toilet of the mouth, nose, anus and meatus urinarius. Bedding, utensils and such articles as may come in contact with the patient should be scrupulously guarded and disinfected. These precautions are valuable and necessary under any and all circumstances, but we are somewhat nonplussed when we have to deal with the human carriers of typhoid bacilli.

All mosquitoes, bedbugs, and fleas, which have sucked the blood of typhoid patients, contain typhoid bacilli.

The virulence and vitality of typhoid bacilli are preserved in these insects. Typhoid bacilli may be found in these insects from eight to twenty-one days after they have sucked the blood of a typhoid patient. The feces of these infected insects contain virulent bacilli as long as they persist in the alimentary canal or in the blood or secretions. Insects which have fed on patients infected by bacilli of high virulence by means of bites convey infection of equal virulence. The local inflammatory reaction of patients to bites of these infected insects is slight, and, in fact, no more than from the uninfected insect. Infected insects may communicate the disease for two or three weeks after infection. The injury to the skin caused by the bites of mosquitoes, bedbugs, or fleas offers an avenue of infection for typhoid bacilli. The bed-linen fabrics, or other material, on which infected insects may be crushed, offers a ready source of infection. All insects which feed on excreta, animal or vegetable material, and which frequent, breed and hatch, in or on, or come in contact with material infected with typhoid bacilli will become carriers thereof.

It may be argued that these insects do not bear a sufficiently important relation to the transmission of typhoid fever to be of value to preventive medicine. It is true that the evidence is not as convincing as it might be, but when we consider the unfavorable conditions under which investigations must necessarily be made it is certainly an important problem well worthy of further study. Occasionally the investigator is enabled to secure insects immediately after they have become infected, but generally he must work with captive insects, using artificial means, in a strange environment. Thus his efforts are often thwarted, and persistence, perseverance, and an immense amount of systematic work is necessary to secure positive results. The isolation of a pure culture of typhoid bacillus from the blood of suctorial insects is no small matter. The isolation of the bacillus from the alvine discharges is even more difficult. Yet these insects are marvelous factors in the dissemination of the typhoid bacillus.

I should like to voice the sentiments of Dr. White as to the importance and significance of the study of entomology by physicians. It is a field practically untilled; yet some of the greatest advances of preventive medicine in modern times are due to the work of those who have labored therein. The pioneer work of Laveran, Manson, Ross, Sternberg and others initiated the campaign against the malaria-bearing mosquitoes. The subsequent researches of Manson and Bancroft have proved that filariæ are transmitted by mosquitoes. The suggestion, based on observations by Dr. Charles J. Finlay of Havana, that mosquitoes might be agents in spreading yellow fever was slightly regarded and even contemptuously received by investigators. It remained for the Army Yellow Fever Commission, in 1900, to report that yellow fever followed the bite of mosquito species, *Stegomyia fasciata.* Eminent investigators (Reed and Lazear of America and Dutton of Liverpool) lost their lives from attacks of the disease they were studying, caused by insects. The work that these pioneers had so nobly advanced has been efficiently maintained by Gorgas, White, and others associated with them in their work.

In this brief account of the rôle that certain insects play in the propagation and dissemination of typhoid fever, only a small part has been told. I believe that within two years observers will be able to find that insects are the disseminating medium of various other diseases. The medical profession and laity are fortunate to have the government bureau of entomology, under the efficient direction of Dr. L. O. Howard, it having made possible many advances in preventive medicine.

The study of entomology and its relation to disease is comparatively recent, and it offers one of the most prolific and promising fields in preventive medicine.

TYPHOID IMMUNITY AND ANTITYPHOID INOCULATION *

WILLARD J. STONE, B.Sc., M.D.
Attending Physician St. Vincent's Hospital
TOLEDO, OHIO

The difficulties attending the diagnosis of mild types of typhoid fever have made the study of the duration of immunity conferred by an attack a perplexing one. The differentiation of typhoid-like, paratyphoid, colon and paracolon infections is by no means easy, even for those so fortunate as to have at their disposal ample facilities for conducting blood culture and agglutination tests against strains of all the bacteria mentioned.

Typhoid simulating mild types of meningitis, early tuberculosis and many pneumonias with delayed resolution, likewise malarial fever (so-called) is frequently overlooked. In our hospital wards one rarely hears, in taking the history of a typhoid case, reference to an earlier attack. Most writers agree that, as in many other acute systemic infections, one attack is sufficient to produce a probable, although not absolute, immunity against later attack. Dreschfeld's figures, based on 2,000 cases in the Hamburg General Hospital, show that only 0.7 per cent. were affected twice. It is extremely probable, however, that the actual incidence of attack in individuals once infected is much greater than these figures indicate because of lack of facility in the way of accurate laboratory and clinical observation in many localities where the disease is prevalent.

The various antibacterial substance elaborated in the blood and the tissue fluids of an infected individual serve, however, in a large percentage of cases to protect against subsequent attack. These antitropic substances, the agglutinins, lysins, bactericidins and latterly the bodies concerned with phagocytosis (the opsonins and stimulins), are distinctly antibacterial rather than antitoxic in their function. The process of immunization in typhoid is, according to present knowledge, a matter of specific reaction on the part of the body cells to the protein molecule making up the cell structure of the bacterium. This reaction is specific for the protein molecule exciting the reaction on the part of the body cells and take place, according to Vaughan and Wheeler,[1] through the liberation of a specific ferment which is activated or liberated through excitation by the proteid in question, whether bacterial, animal or vegetable. Such specific reaction in the process of immunity protects only against the specific proteid derivative which calls it forth; that is to say, the proteid derivatives obtained from colon bacilli protect, when inoculated, only against colon bacilli. The reaction is specific in the sense that the antibacterial substances elaborated under the influence of an infection are protective only against that infection.

THE BLOOD CHANGES DURING AND FOLLOWING AN ATTACK OF TYPHOID FEVER

Agglutinins.—During the second week of typhoid fever the agglutinins, in accord with general experience, are increased so that, on an average, the serum will agglutinate typhoid bacilli in dilutions from 1 in 100 to 1 in 200, exceptionally 1 in 400 or higher. After the decline of the fever there is rapid decrease in agglutinative value, the average being 1 in 60 or 1 in 80. For a few months to one year or longer this value remains low at about 1 in 40 to 1 in 60. (In my own case eighteen months after an attack of typhoid the serum would agglutinate in dilutions of 1 in 60.) Exceptionally a very high agglutinative value may be obtained as mentioned by Leishman and Harrison,[2] who refer to one patient whose serum, six months after the commencement of the illness, would agglutinate in dilutions of 1 in 1000.

Bactericidins.[3]—The bactericidal powers are increased, on an average, two or three times above the normal (which has more or less bactericidal power in dilutions from 1 in 10 to 1 in 20) during the first few weeks after the commencement of an attack. This power gradually falls at the decline of the fever so that the normal is reached at above the fourth month. Fatal cases may show a relatively high bactericidal power.

Opsonins.[4]—In contrast to the low bactericidal power of serum obtained during the decline of the fever and afterward, the opsonic index is relatively high. During the first few weeks of the fever the index is increased to 1.5 to 3.5. There is usually a slight decline during convalescence, although occasionally high indices may be obtained at this time. As a rule a high index, from 2 to 3, is found to persist for months after an attack. The only fatal case (bowel perforation at the end of the second week) I have been able to follow had a low index of 0.6 from the beginning. The general impression is that cases manifesting a persistently low index have a less favorable prognosis. This may be true for the patients who die in typhoid from exhaustion, a relatively small number, when compared with those dying from hemorrhage or perforation. It is conceivable, on the other hand, that a low phagocytic power to destroy bacilli locally is responsible for extensive necrosis of an intestinal ulcer leading to such erosion as eventually favors hemorrhage or perforation.

Stimulins.—Heating a serum to 60 C. renders the opsonin it contains inert, at least for some strains of typhoid bacilli. On the other hand, some strains are more readily phagocytable when the serum is heated to 60 C. The substance remaining in the blood serum heated to 60 which is still capable of inducing phagocytosis has been called "stimulin." It is more stable than opsonin. In some cases cited by the Royal Army Commission, heated serums showed double the power to activate phagocytes over that obtained with unheated serums. The only statistics available in this connection are those of Leishman and Harrison,[2] who estimated the stimulin value of the serums of thirty-five typhoid patients by adding a small amount of their heated serums to heated normal serum which was then tested as to its power to stimulate the phagocytic activity of normal leucocytes. During convalescence and afterward the stimulin curve rises considerable above normal to 2 or 2.5, at about which points it is maintained for months after the attack.

[3] To determine the bactericidal power of a serum progressive dilutions are mixed with a measured quantity of twenty-four-hour broth culture of bacilli and allowed to remain in the incubator at 37 C. for fifteen minutes. Agar plates are then inoculated with the mixture and the number of colonies which develop after twenty-four hours are estimated.

[4] It makes some difference in the results obtained whether one uses the method of Wright or Klein in estimating the index; also whether a virulent or non-virulent strain is used for the bacterial emulsion.

PREPARATION OF ANTITYPHOID VACCINE

The early history of antityphoid inoculation concerned itself with the same problems which led up to the Pasteur methods of inoculation against rabies and anthrax or to the anticholera inoculations of Haffkine; i. e., by the use of attenuated living virus. Such methods of procedure in typhoid prophylaxis have seemed to be quite beyond the necessity of its scope. The pioneer work of Prof. R. Pfeiffer,[5] in 1896, who was able to obtain a specific agglutinin reaction in man by the injection of heated typhoid culture in two cases, led, through a personal communication to A. E. Wright, to the experimental work and the publishing of the results of two inoculations by him.[6]

To Wright belongs the credit of placing the method on a rational basis through many thousand preventive inoculations made in the British army in India and during the Boer War. The investigations carried on in the laboratories of the Royal Army Medical College under Leishman, as well as the stamp of approval placed on the results obtained by the Royal Army Commission and the Royal College of Physicians, to which was referred the question of the efficacy of antityphoid inoculation, has done much to dispel the skepticism with which it was first regarded.

Wright's method, with slight modification, has been followed since that time. In general as in the preparation of other bacterial vaccines the following principles are followed: 1. The vaccine must be capable of stimulating the production of protective typhocidins, lysins, agglutinins and opsonins (typhoid and cholera differ from many other acute infections in that bactericidins and bacteriolysins are largely limited to them). 2. The vaccine must not be so altered in its preparation by heat or chemical agents as to impair its immunizing properties. 3. The dosage employed must be sufficient to maintain a phase of increased resistance to infection for a considerable period.

In the earlier work the vaccine was prepared as follows: Broth cultures of non-virulent typhoid bacilli, after from 10 to 21 days' growth at 37 C., were standardized and exposed to a temperature of 60 C. for fifteen minutes, after which 0.45 to 0.50 per cent. phenol was added for purpose of preservation. Broth cultures cultivated for from ten to twenty-one days undergo considerable autolysis so that standardization is difficult, so that more recently twenty-four-hour broth cultures have been used (agar cultures twenty hours old may be used in the preparation of vaccine on a smaller scale). Overheating greatly impairs the immunizing properties of the vaccine. The thermal death point of most strains of typhoid bacilli is 53 C. (occasionally one may meet with an exceptionally resistant strain) at which point, at present, the bacterial suspension is maintained for one hour.

The addition of phenol or liquor cresolis compositus to the vaccine when hot destroys its immunizing efficacy. Liquor cresolis compositus (0.25 per cent.), which is largely used, is sufficient to preserve the vaccine against contaminating anaërobes or spore-bearing bacteria. Phenol is in some respects superior to liquor cresolis compositus, since the cloudy, at times clumpy, masses found in some cresolized salt solutions are avoided. I have more recently avoided heat in the preparation of the vaccine. Harrison[7] has shown that 0.2 per cent. compound solution of cresol is sufficient to inhibit the growth of typhoid bacilli in broth, while Leishman and his co-workers[8] have shown that 0.25 per cent. liquor cresolis compositus added to unheated typhoid vaccine is sufficient of itself to render it sterile in twenty-four hours. Moreover, vaccine prepared by the simple addition of liquor cresolis compositus without heat is capable of inducing in rabbits a rise in agglutinins, bactericidal substances and in substances concerned with phagocytosis. I have more recently added 0.4 to 0.5 per cent. phenol in normal salt to the bacterial suspension *without* heat in the preparation of the vaccine. The vaccine is sterile in forty-eight to seventy-two hours. Such vaccines seem to produce a rise in the antibodies concerned with immunization in smaller dosage than vaccines killed by heat. On the other hand, it should be noted that heating a typhoid vaccine to 53 C. for one hour does not impair it.

Along this line it may be of interest to mention certain results obtained with other chemical agents used to devitalize bacterial vaccines without heat. Acetozone in saturated solution, 1 to 1,000, was used as a diluent. A suspension of three strains of typhoid bacilli containing approximately 5,000,000,000 per c.c. was diluted with twenty volumes of acetozone, 1 in 1,000. The suspension was sterile in forty-eight hours. Doses of this vaccine when inoculated in one individual produced after fourteen days an agglutinative reaction in one-half hour after administration, with a 1 in 500 dilution of the serum.

Acetozone, 1 in 1,000, in doses of 1 to 2 c.c., is non-irritating when injected subcutaneously. A 1-in-2,000 acetozone solution failed to sterilize a vaccine made from an avirulent strain in five days. A saturated chloretone (0.5 to 0.7 per cent. with heat) in normal salt (after a suggestion by Dr. Willard H. Hutchings) would sterilize unheated bacterial suspensions of typhoid containing 1,000,000,000 and 2,000,000,000 per c.c., respectively, in twenty-four hours, but the vaccine containing 2,000,000,000 per c.c. germinated and a diffuse growth on agar was obtainable after seventy-two hours, while the 1,000,000,000 vaccine was still sterile after ten days.

Macfadyen[9] suggested in 1903 a method of preparing typhoid vaccine by trituration and grinding, such as is used in the preparation of Koch's new tuberculin. Such a method, without the security of sterilization, involves the risk of transmitting infection and does not produce a more potent vaccine. Among the other methods which have been tried may be mentioned the use of "washed bacteria" as a vaccine; bacterial suspensions killed by chloroform vapor, and vaccine killed by the addition of 20 per cent. neutral glycerin. All of those methods produce a rise in the substances concerned with acquired immunity, but no more effectively than the standard vaccine. Harrison has used typhoid bacilli in glycerin emulsion by mouth, also sterile typhoid bacilli suspended in fat and enclosed in gelatine capsules, by mouth. Although it appeared possible to increase slightly the antibacterial elements in the blood by such methods of administration the results, on the whole, were not as satisfactory as those obtained by subcutaneous inoculation.

THE RELATIVE EFFICIENCY OF VACCINES PREPARED FROM VIRULENT AND NON-VIRULENT STRAINS

The earlier work done with various strains of typhoid bacilli, as in the preparation of other vaccines, seemed to convey the impression that virulent strains, when injected, produced a more decided rise in protective antibodies than vaccines prepared from non-virulent, long-cultivated strains. This impression has not been borne out by facts. A typhoid vaccine prepared from a single non-virulent strain is quite as capable of inducing a sufficient immunizing response as vaccine prepared from two or more virulent strains. This protection exists against other non-virulent strains and also against single or multiple virulent strains.

DURATION OF POTENCY OF TYPHOID VACCINES

Typhoid vaccine six months or more old is apt to lose a considerable amount of its immunizing potency. Vaccine three months old has been found by Leishman and Harrison to be as potent as when freshly made.

To be on the safe side, vaccine not over three or four months old should be used. Extreme degrees of heat or cold seem to affect the immunizing qualities of a vaccine if kept for a considerable period under such conditions. Room temperatures seem best suited for preservation.

METHOD OF ADMINISTRATION AND DOSAGE: THE LOCAL AND GENERAL REACTION

Although a considerable immunity results from one inoculation of 500,000,000 to 1,000,000,000 bacilli, this immunity may be much augmented by a subsequent injection of 1,000,000,000 ten to fourteen days. The Royal Army Commission, appointed in October, 1904, found that an interval of about ten days should separate the doses. The first dose consists of 500,000,000 to 1,000,000,000 and the second from 1,000,000,000 to 1,500,000,000. The injections are conveniently given subcutaneously on the outer side of the upper third of the arm near the point of insertion of the deltoid, or subcutaneously in the abdominal wall. The needle should not puncture the muscle, as pain is produced and a considerable local reaction follows. The site of injection usually becomes reddened and slightly tender to touch, but these local manifestations disappear in about twenty-four hours. The first dose of vaccine does not, in my experience, produce any marked degree of reaction, local or general. Occasionally in a hypersusceptible subject the general reaction is severe. This is manifested by a feeling of malaise and headache with more or less general muscular aching and a temperature which may reach 100 or 101 F. for a few hours. This general reaction is more apt to occur after the second injection of 1,000,000,000 to 1,500,000,000, but it disappears within twenty-four hours. Patients are seldom required to give up their work. The best time for administration of the vaccine is in the late afternoon so that rest may be secured early in the evening.

THE BLOOD CHANGES AFTER PREVENTIVE INOCULATIONS AND THE DURATION OF IMMUNITY

Agglutinins.—The agglutination curve begins to rise about nine days after an inoculation and reaches on an average 1 in 500 to 1 in 1,000 by the tenth or eleventh day. The average has been about 1 in 500 in my cases. Occasionally a very high agglutinative point may be reached as in a case cited by Shoemaker,[10] in which eleven days after the first inoculation agglutination was obtained in a dilution of 1 in 12,800.

The immediate effect of the second inoculation may be temporarily to lower the agglutinative value reached as a result of the first inoculation, for twenty-four to thirty-six hours, but the value is then increased, reaching in some cases 1 in 1,200, 1 in 1,500, to 1 in 8,000. Such a high point may be maintained for a number of months, but a decline manifests itself within a year, at the end of which time the serum will usually agglutinate bacilli in dilutions of 1 in 100 or 1 in 200. Harrison has reported agglutinin reactions in dilutions of 1 in 30 four years after inoculation and complete reactions in dilution of 1 in 20 after six years.

Bactericidins.—The bactericidal substances are increased fourfold or fivefold by the inoculations. There seems to be less decrease in these substances after considerable time than in the agglutinin value of the serum. For example, Harrison has found the bactericidal value four times the normal one year after inoculation; three or four times the normal after four years, and two and one-half times the normal after six years.

Bacteriolysins.—The bacteriolytic substances are likewise increased. Serums from inoculated subjects diluted 1 in 5 to 1 in 10 and mixed with living typhoid bacilli cause either complete disappearance of the organisms or their reduction to amorphous masses.

Opsonins and Stimulins.—The opsonic index is markedly increased, reaching often 2 or 2.5 after the first and 3 to 5.5 after the second inoculation. Stimulins are also increased; serum after the inoculations when heated to 60 C. gives from one and a half to two times the power to activate phagocytes over that shown by unheated serum. In general the results obtained by Leishman and Harrison agree with those obtained by Klein,[11] who found, by dilution experiments, in immunizing rabbits by subcutaneous injections of living typhoid bacilli, that opsonins were considerably augmented. He also found that typho-agglutinins and lysins were increased and comparatively, that the opsonins and lysins increased more rapidly than agglutinins. The discrepant results obtained, as regards the opsonins, have been shown by Clark and Simonds[12] to be due to the use of different strains of organisms. Markedly divergent results may be obtained using different strains with the same serum. In fact, some strains, when freshly isolated, may give considerable spontaneous phagocytosis, while repeated transplantation of strains which do not induce spontaneous phagocytosis may render them very susceptible to phagocytes in the absence of serum. One strain virulent to rabbits may give a lower opsonic index with rabbit serum than a non-virulent strain, while again with the same serum another virulent strain may give a higher index than the non-virulent strain.

The duration of immunity produced by preventive inoculations has been variously estimated at from two to six years. In many cases the immunity probably lasts for life, although of this conjecture no definite proof exists. Whether the immunity following the inoculations in man is sufficient to ward off infection with virulent typhoid bacilli is not known. The striking preponderance of the substances which have to do with phagocytosis (opsonins and stimulins) stand out more clearly as evidence of increased protection following preventive inoculations than the other bacteriotropic substances concerned with this form of acquired immunity.

THE PROTECTIVE POWER OF ANTITYPHOID VACCINE AGAINST PARATYPHOID INFECTION

Since the substances concerned with acquired immunity to typhoid have been shown to be largely those which pertain to phagocytosis, the opsonins and stimulins, it becomes a matter of interest to know whether the injection of antityphoid vaccine increases the phagocytic stimulating activity of the blood serum against paratyphoid infection. Clark and Simonds[12] find that "opsonins arising in typhoid fever are generally, if not constantly, equally capable of stimulating phagocytosis of paratyphoid bacilli," and, moreover, that the injection of either typhoid or paratyphoid vaccine caused a rise in the opsonic index for both organisms in rabbits. The index gradually increased after each injection. On the other hand, Leishman and his co-workers did not find that inoculations of antityphoid vaccine in man produced any increase in the phagocytic value or, for that matter, any increase in agglutinins or bactericidins, when tested against two strains of paratyphoid bacilli. In the light of these differences it may be concluded that the matter of protection against paratyphoid fever afforded by injections of antityphoid vaccine has not been settled.

CONDENSED STATISTICS RELATIVE TO ANTITYPHOID INOCULATION IN THE BRITISH ARMY AND THE ADOPTION OF THE PROCEDURE IN THE U. S. ARMY

Leishman[13] has recently given the results of inoculation in the second battalion of the Royal Fusiliers in India from December, 1904.

TABLE 1.—Results of Inoculation in One Battalion

Strength of Regiment.	No. Inoc.	Admitted to Hospital to Date. Non-inoculated. Cases.	Deaths.	Inoculated. Cases.	Deaths.
12/31/1905, 883	103	2	0	0	0
12/31/1906, 1013	181	35	5	9	0

The statistics of the Seventeenth Lancers in India from October, 1905, are also very favorable. In a regiment varying from 508 to 680 men, 425 men were inoculated with antityphoid vaccine from October, 1905,, to May 1, 1907. Among the inoculated men during this period, two developed typhoid with no deaths, while among the non-inoculated men there occurred 69 cases of typhoid with eleven deaths. Among the inoculated men, each of the two in whom typhoid occurred had refused to take the second dose of vaccine, which in the case of this regiment was prepared at 53 C. No case of typhoid has occurred in this regiment among the men who received two inoculations of this vaccine. In seven large India regiments the results have been as shown in Table 2.

TABLE 2.—Results of Inoculation in Seven Regiments, January 1 to June 30, 1907

	Strength.	Cases.	Deaths.	Incidence Per 1000	Mortality Per 1000
Non-Inoculated..	8113	173	42	21.32 (+1.08)	5.18 (+0.54)
Inoculated......	2207	15	3	9.80 (+1.18)	1.36 (+0.53)

The latest statistics in the British army[14] up to June 1, 1908, relative to prophylactic inoculation are as follows: Among 12,083 men comprising sixteen regimental units, 5,473 were inoculated. These regiments were stationed in India, Egypt, Malta, Crete, South Africa, etc. The case incidence per thousand, taken as a whole, among the inoculated men, was 3.8, while among the non-inoculated men the case incidence per thousand was 28.3. Among those sixteen units in which typhoid occurred (typhoid did not occur in some of the regiments) the case incidence per thousand among the inoculated men was 6.6, while among the non-inoculated men the case incidence per thousand was 39.5.

In the U. S. army, the work begun last December, as a result of the conclusions reached by the medical board appointed for the purpose, is well under way. This board consisted of Surgeon-General O'Reilly, V. C. Vaughan, W. T. Councilman, J. H. Musser, A. Lambert, Simon Flexner, W. S. Thayer and Major F. F. Russell, of the Medical Corps, U. S. Army. The conclusions reached by them are as follows:

1. The board is convinced that the practice of antityphoid vaccination is both useful and harmless, and that it offers a practicable means of diminishing the amount of typhoid fever in the army, both in times of peace and war.
2. It finds that the experience to date with antityphoid vaccination justifies it in recommending the introduction of the practice in the regular and volunteer armies in time of war.
3. It recommends the immediate introduction of the practice of vaccination against typhoid in the Hospital Corps, the Army Nurse Corps, and in any expedition of troops from the regular army which is ordered to take the field for active operations; and further, that an opportunity be given to volunteers from the army as a whole to be protected by vaccination against typhoid.

The vaccination work is under the charge of Major Russell, of the Medical Corps, and is entirely voluntary.

THE INOCULATION OF ANTITYPHOID VACCINE IN TYPHOID-CARRIERS. IN ENDEMIC AND EPIDEMIC AREAS. GENERAL CONCLUSIONS

Investigations have established that about 4 per cent. of convalescent typhoid cases become chronic "typhoid-carriers," disseminating the infection more or less constantly with the feces and urine for periods of years.

Where new cases of the disease can, with fair degree of presumption, be traced by appropriate bacteriologic tests to such individuals, especially cooks, dairymen or dairymaids, workers in confectionery, waiters and waitresses or those who have to do with the handling of food in any way, the inoculation of antityphoid vaccine offers a more certain means of raising the bacterial resistance in such individuals than any other known method of treatment.

The method of antityphoid vaccination involves no risk and is especially applicable for those constantly exposed to infection, such as nurses, hospital attendants and physicians.

Antityphoid inoculations should be avoided if possible in individuals during the incubation stage of typhoid, for, although it is probable that the stage of diminished resistance (negative phase) for a few days following the inoculation is more theoretical than real, it is more wise, in the present state of knowledge, to avoid the possibility of cumulation.

In endemic areas, where a considerable proportion of the population annually suffers the infection, or in epidemic areas, where there is reason to suppose the possibility of widespread infection, inoculations of antityphoid vaccine are indicated in individuals not in the prodromal or incubation stage of the disease.

EPIDEMIOLOGIC STUDIES OF TYPHOID FEVER *

L. L. LUMSDEN, M.D.
Passed Assistant Surgeon, U. S. Public Health and Marine-Hospital Service
WASHINGTON, D. C.

PREVALENCE OF TYPHOID FEVER IN THE UNITED STATES

Judging by obtainable figures, there are in the United States comparatively few communities of over 1,000 persons which during any period of twelve consecutive months within the past ten years have been entirely free from typhoid fever. The extensive prevalence of this thoroughly preventable disease in our country as a whole is beginning to be justly considered a national disgrace.

Communities, like individuals, seem to be as a rule unable to profit by the experiences of others, and the history of typhoid fever is replete with instances of communities having failed to carry out clearly indicated preventive measures until the occurrence among them of severe epidemics has caused an awakening.

NATURE AND SOURCE OF THE INFECTIOUS AGENT

At present the generally accepted view is that typhoid fever is an infectious disease caused by a specific parasitic organism, the typhoid bacillus. The undetermined elements in the causation of the disease are those concerned in the establishment of individual susceptibility to the infection and, in some instances, those concerned in the transmission of the infection. All known facts on the subject support the view that man is the permanent host of the parasitic organisms which cause typhoid fever, and that if their multiplication in and their dissemination by the human host could be prevented these organisms would soon perish from the earth. Therefore, what appears a sound belief, based on epidemiologic findings, is that "each and every case of typhoid fever comes somehow from some previous case." (Sedgwick).

PREVENTION OF INFECTION

The specific parasite which causes typhoid fever and its permanent host being known, an apparently simple formula to prevent the disease is to destroy the infection as it leaves the bodies of infectious persons. Could such a plan of action be made sufficiently wide in scope it would promise success; but the people of a given community may use water, milk and various foodstuffs obtained from a distance and liable to contamination with the excreta of infectious persons over whom their own health officials have no jurisdiction. Therefore, for the local health officer the two principal plans of action to prevent typhoid fever in his community should be the following:

1. The discovery of and the prevention of the spread of infection from persons in his community who harbor infection (typhoid fever patients and bacillus-carriers).
2. The prevention of the introduction of infection into his community from without through various channels, such as the water-supply, milk-supply, and the general food-supply.

DETERMINATION OF IMMEDIATE SOURCES OF INFECTION

In order to determine the principal immediate sources of the infection in a locality careful epidemiologic studies are necessary. Explosive outbreaks, such as those produced by highly infected water or milk, present rather characteristic features, and as a rule epidemiologic studies of these will point out quite readily and definitely the source of the infection. But in communities where a high rate of prevalence of typhoid fever is maintained for years and is due to a number of different factors which vary in relative extent of operation from time to time, the problem becomes very intricate and its exact solution exceedingly difficult.

Studies of all typhoid fever situations, however, should be conducted along the same general lines. Hasty conclusions, based on first-glance impressions, should be avoided. Every factor possibly concerned in the spread of the infection should be carefully considered and investigated. As the facts are collected one factor after another may be eliminated, until definite conclusions may be drawn as to the principal source, or sources, of the infection.

DIFFERENT TYPES OF TYPHOID FEVER SITUATIONS PRESENTED FOR STUDY

Large urban communities in which the disease has prevailed for a long time as a rule present complex typhoid fever situations. Here the conditions of life are complex. Large numbers of all classes of people are in close association. Foodstuffs are obtained from many sources and handled by many persons. In some instances the water-supply is obtained from a number of different sources. Small communities, usually free of the disease, when visited by sudden and extensive outbreaks, present, as a rule, simple typhoid fever situations.

During the last three years as a member of a board of officers[1] detailed by the Surgeon-General of the Public Health and Marine-Hospital Service to study the origin and prevalence of typhoid fever in the District of Columbia, I have been engaged in a study of a situation of the complex type; and recently I have conducted an investigation of an outbreak at the National Park Seminary at Forest Glen, Md., which was of the simpler type of typhoid fever situation. These two situations may be presented as a striking contrast:

THE TYPHOID FEVER SITUATION IN WASHINGTON, D. C.

Previous to 1906 there was quite a general consensus of opinion among those who had given attention to the subject that the high rate of prevalence of typhoid fever in Washington was due to the polluted public water-supply obtained from the Potomac River.

Effect of Filtration of the Public Water-Supply on the Typhoid Fever Rate.—In October, 1905, a filtration plant was completed and since then the city has been supplied continuously with filtered Potomac River water. During the winter and spring months following the installation of the sand filters there was comparatively little typhoid fever in Washington, but early in July, 1906, there occurred a great increase in the number of cases and the disease was properly regarded as prevailing in epidemic form.

This marked increase in the prevalence of typhoid fever with the advent of summer weather corresponded with the history of the disease in many previous years. The typhoid fever death rate for the calendar year 1906 was 49.3 per 100,000, while for the three years immediately previous to the filtration of the water it averaged about 44 per 100,000. Thus, the rate in 1906, the first year after the filtration of the water, was somewhat in excess of the rates of the several years previous, despite the fact that the results of the bacteriologic analyses of the water showed that the filtration accomplished a very great reduction in the total bacterial content of the applied water such as was supplied to the city during the three years previous to filtration. In 1907 and 1908, the second and third years after filtration, the typhoid fever case and death rates in Washington were lower than in any other years of which there is record The typhoid fever death rate in 1907 was 34.5 and in 1908 36.5 per 100,000. The reduction in the rate in these two years is accounted for by the reduction which occurred in the summer typhoid. The rates in the winter, spring and fall seasons of the three years 1906, 1907 and 1908 were almost exactly the same.

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] Surgeon M. J. Rosenau, chairman; Passed Assistant Surgeon L. L. Lumsden; and Prof. Joseph H. Kastle, recorder.

An important question and one difficult to answer positively is: How much, if any, of the reduction in the typhoid fever rate in the summers of 1907 and 1908 was due to the improvement in the water-supply as the result of sand filtration? Had such a reduced rate been observed in the summer of 1906, the first year after the filters were put into operation, probably few if any would have doubted that the reduction in the summer typhoid had been accomplished by the improvement in the water supply.

Judged by bacteriologic standards we found the filtered water supplied the city in the summers of 1907 and 1908 was of considerably better quality than the filtered water supplied the city in the summer of 1906. The fact that the higher degree of improvement of the filtered water was followed by a reduction in the typhoid rate, to my mind, suggests cause and effect.

As a board we have not been able to decide definitely as to what part water-borne infection played in the causation of typhoid fever in Washington in 1906; but we are satisfied, by the results of our studies, that the Potomac River water previous to filtration caused much less of Washington's typhoid than was generally supposed, and that in the summers of 1907 and 1908 the public filtered water-supply played a relatively minor rôle, if any, in the causation of the disease.

Milk.—In the typhoid fever seasons (May 1 to November 1) of each of the three years, 1906, 1907 and 1908, we have definitely attributed about 10 per cent. of the cases originating in the District of Columbia to milk-borne infection. These cases occurred in the course of pronounced milk outbreaks among the customers of certain dairymen.

In the season of 1906 there were three such outbreaks, in the season of 1907 one, and in the season of 1908 one. The outbreak in the fall of 1908[2] was of particular interest, inasmuch as the infection was traced to a bacillus-carrier who was engaged in handling the milk on one of the farms from which the implicated supply was obtained. This woman gave a history of having had typhoid fever about eighteen years before and of having been since then in robust health.

Besides the cases which have occurred in the course of pronounced milk outbreaks we believe that there have been a number of scattering cases due to infected milk which we have not been able to trace, and we consider milk one of the major factors concerned in the transmission of typhoid fever in Washington.

Contact.—In the cases originating in the District of Columbia during the typhoid seasons of 1907 and 1908 about 20 per cent. of the patients gave a history of more or less direct or indirect association, during the thirty days previous to onset of illness, with previous patients in the febrile stage of the disease and were attributed to infection by contact.

Considering the large amount of association between persons living in a large city and the number of ways in which infection through personal contact may occur it is easy to understand that many cases in a large city may be due to infection by contact which can not be traced, and I regard personal contact as one of the major factors concerned in the transmission of typhoid fever infection in the District of Columbia.

Imported Cases.—About 24 per cent. of the cases of typhoid fever which were reported in the District of Columbia during the typhoid seasons of 1907 and 1908 were cases in which the infection had been contracted outside the District of Columbia. In the 1906 period the imported cases amounted to about 15 per cent. of the total.

Intricacy of the Washington Problem.—A number of interesting details as to seasonal prevalence, racial distribution, relation of the seasonal abundance of flies to the seasonal prevalence of the disease, etc., have been worked out, but they are set forth in the publications[3] and enough has been cited to indicate the great intricacy of the typhoid fever problem in Washington.

There is no mystery as to why Washington has some typhoid fever, but there does seem to be some mystery as to why Washington still has so much typhoid fever. For a city having the climatic and general sanitary conditions of Washington and having no water-borne infection a typhoid death rate of 35 per 100,000 per year does seem comparatively high.

The "excessive" typhoid rate in Washington presents an interesting field for speculation, such as (1) the possibility that the public water-supply, though not distributing typhoid bacilli, does convey some other agents which have to do with the establishment of susceptibility to typhoid infection; (2) the possibility of there being peculiarly active in Washington some as yet entirely unknown agent or agents which are concerned in the dissemination of the infection.

The fact that communities which have good water, a properly safeguarded milk-supply, a good sewerage system, and in which cases of the disease are properly cared for, have little or no typhoid fever indicates either that there are no unknown agents much concerned in the spread of the infection or that the same measures which prevent the operations of the known agents also prevent the operation of whatever unknown agents there may be.

In considering the "excessive" typhoid fever rate of Washington it should be borne in mind that climatically Washington is a southern city and that there are few, if any, cities of over 75,000 population south of Washington and east of the Mississippi river which during the two years 1907 and 1908 had typhoid fever rates as low as that of Washington.

AN OUTBREAK OF TYPHOID FEVER AT THE NATIONAL PARK SEMINARY, FOREST GLEN, MD.

In the latter part of March, 1909, an outbreak of typhoid fever occurred at the National Park Seminary, a school for young women located at Forest Glen, Md., a village about nine miles from Washington, D. C. Twenty-four cases developed.

---

[2] Lumsden, L. L., and Woodward, William C.: A Milk-borne Outbreak of Typhoid Fever Traced to a Bacillus-Carrier, THE JOURNAL A. M. A., March 6, 1909, lii, 749.

[3] Rosenau, M. J., Lumsden, L. L., and Kastle, J. H.: The Origin and Prevalence of Typhoid Fever in the District of Columbia, Rep. 1, Hyg. Lab. Bull. 35, U. S. P. H. and M.-H. S., Washington, 1907 [Season of 1906]; Rep. 2, Hyg. Lab. Bull. 44 [Season of 1907]; Rep. 3, Hyg. Lab. Bull. 51 [Season of 1908].

The first patient began to have slight prodromal symptoms about March 10 and developed definite symptoms and took to bed on March 19. The last patient began to complain about April 16 and developed definite symptoms and took to bed on April 21. The occurrence of cases by definite onset of symptoms was as follows:

	Cases		Cases
March 19	1	April 9	2
March 24	1	April 10	1
March 25	2	April 12	1
March 29	1	April 13	1
April 3	1	April 14	1
April 4	2	April 15	1
April 5	4	April 21	1
April 6	3		
April 8	1	Total	24

A fairly large proportion of the cases ran a mild course. Only one death occurred, making a fatality rate of 4.17 per cent. In the majority of the cases the diagnosis was confirmed by positive Widal test or by isolation of the typhoid bacillus from the blood, feces or urine.

Some of the students developed the disease at the seminary and others in different sections of the country to which they had gone for the Easter holidays.

Distribution of the Infection.—At the time of the occurrence of the outbreak the population of the seminary consisted of about 400 persons as follows:

Students	270
Officials and instructors	35
Employés and servants—	
White men	15
White women	35
Colored men	45
Total	400

The 24 cases were distributed among the seminary's population as follows: 20 in students, 1 in officials and instructors, and 3 in employés and servants. Thus the distribution of the disease among the three classes was quite general.

The grounds of the seminary cover about sixty acres. The buildings are all of modern construction and are kept in excellent sanitary condition. The four buildings occupied by the students are located in different parts of the grounds. The number of students to each building and the number of cases of typhoid fever which developed among them were as follows:

	No. of students.	No. of cases.
Main building	145	10
Villa	50	7
Junior building	35	3
Senior building	40	0

The three buildings occupied by employés and servants, with the number of occupants and cases to each, were as follows:

	No. of occupants.	No. of cases.
Building for white women	35	2
Building for white men	15	0
Building for colored men	45	1

Again, it was evident that the disease was generally distributed throughout the population regardless of building occupied as place of residence.

Previous Typhoid.—The seminary was established in 1894. No cases of typhoid fever developed among the persons living at the seminary until the beginning of the school term in the fall of 1908. Then two of the students developed definite symptoms of typhoid fever, one sixteen days and the other twenty-three days after arrival at the seminary. As no other cases occurred it was presumed that probably both of these students contracted the infection before coming to the seminary.

In the summer of 1908 three cases developed among the students about three weeks after they had left the seminary and gone for the summer vacation to their homes in different parts of the country. In these cases, also, the infection may have been contracted when the young women were *en route* to or after their arrival at their homes.

Place of Infection.—The first seven cases to occur in the outbreak were all among the students. As the students made trips to Washington about twice a month and on these trips usually took luncheon in the city, the first question to arise was if the infection had been contracted at the seminary or in Washington.

As a member of the typhoid fever board of the Public Health and Marine-Hospital Service engaged in the investigation of the disease in the District of Columbia, I was aware of the rate of prevalence of typhoid fever at that time in Washington and, as the rate among the students even then far exceeded the rate in Washington, and as reference to our case cards showed that there had been no disproportionately large number of cases among persons in Washington who had taken meals at the restaurants frequented by the students, there seemed at the beginning of the investigation little room for doubt that the infection had been contracted at the seminary. The subsequent extent of the outbreak proved the correctness of this impression.

Investigation of the Outbreak.—On March 30 the typhoid fever board of the U. S. Public Health and Marine-Hospital Service was requested by the authorities of the seminary to investigate the outbreak and to suggest corrective measures. This request was approved by the State Board of Health of Maryland, and on April 7 I visited the seminary and began the investigation.

On March 30, when first consulted in regard to the situation, however, I had advised that all milk supplied the institution be boiled or pasteurized previous to use and that the part of the water-supply obtained from a spring stream which, from its description, was considered liable to dangerous pollution, be discontinued unless this water could be boiled previous to use. The milk-supply was boiled on and after March 31; but some of the water from the spring stream was used until April 8.

At the time the investigation was begun the population of the seminary was about 150, about 230 students, and about 20 employés having left the seminary on or about April 3 and gone for the Easter holidays to various parts of the country. Seven cases of typhoid fever were then known to have developed between March 19 and April 6, five of the cases having been among the students who had remained at the seminary and two among those who had gone away.

Possible Sources of Infection.—After a careful inquiry the following possible sources of infection were found to have been common to the cases then known of:

1. Water-supply.
2. Milk-supply.
3. Bacillus-carriers among servants who prepared or handled foods.
4. Fruits and vegetables such as are eaten uncooked and other food-supplies.
5. Ice.

No raw shell-fish had been served at the seminary during the three months previous to the outbreak. So these could be definitely excluded.

Ice.—The ice had been obtained from one of the large factories in Washington and there had been no unusual number of cases among persons in Washington who used ice from that source. So the exclusion of ice as a factor was quite definite.

Food-Supplies.—The fruits and vegetables and other food-supplies had been bought from dealers in the large markets of Washington and Baltimore; and, as there was no unusual occurrence of typhoid fever among other customers of these dealers, the exclusion of the market supplies as a factor was quite definite.

Bacillus-Carriers.—The explosive character of the outbreak argued against a bacillus-carrier being the source of the infection. It was difficult to conceive how infection from a bacillus-carrier could have been disseminated so generally throughout the seminary's population in so short a time unless the bacillus-carrier was among those concerned in preparing or handling the food in the store-rooms or kitchen from which the meals for the whole population were served. Therefore, specimens of feces and urine from the sixteen servants engaged as cooks, store-room men, dish-washers or waiters were obtained and examined bacteriologically at the hygienic laboratory of the Public Health and Marine-Hospital Service. All the specimens were negative for the typhoid bacillus.

Milk-Supply.—The milk-supply during the four years previous to the outbreak had been received from a farm in the neighborhood. The farm is located on a high hill and is quite well isolated. No history of any illness on the farm to account for the infection was obtainable. Of the twelve persons at the farm none had ever had typhoid fever, all used the milk freely, and none had been sick. There had been no recent changes made among those who collected and handled the milk. The water-supply used for washing the milk-cans, etc., was obtained from a well located on the summit of a hill. A sample of water from the well was examined bacteriologically and found to be of good quality. Thus there seemed to be no reason for suspecting the milk-supply.

One of the cases developed 22 days after the milk-supply had been boiled; which fact, though by no means positively excluding the milk, yet is some evidence against it, as the incubation period in cases due to milk-borne infection usually is considerably less than 22 days.

Water-Supply.—The water-supply was obtained from two sources: (*a*) Three bored wells, each about 90 feet in depth, supplied most of the water used for drinking. The water from these wells was examined bacteriologically and found to be of good sanitary quality. (*b*) A small creek running through the seminary grounds supplied the water used for bathing, for washing dishes, and by the students and others frequently for brushing their teeth and sometimes for drinking. This creek had its source in a spring about half a mile above the intake for the seminary's supply.

The creek was found to be quite highly polluted with human excreta. Emptying directly into it about 100 yards below the spring was the sewage from a hospital in which there were thirty to forty persons. Besides this, some of the sewage from about fifteen residences located on the water shed of the creek between the spring and the seminary's intake evidently was washed or drained into the creek. The physician in charge of the hospital stated that there had been no case of suspected typhoid fever in the hospital. In one of the houses on the water shed, however, there had been a man ill with typhoid fever in February; his excreta, after treatment with copper sulphate—probably not sufficient to disinfect them thoroughly—were thrown out into the yard. This yard is on the crest of a hill which forms one shed of the creek. A roadway and a somewhat poorly defined gully run from the side of the yard down the hill to the creek, a distance of about 400 yards. It was evidently possible that some of the excreta from this patient could have been washed by the heavy rains and melting snows which occurred in the latter part of February and early part of March down the hill and into the creek.

Bacteriologic examination of the water from the creek showed it to be highly polluted, the colon bacillus being invariably demonstrated in quantities of 0.1 c.c. Specimens of the water collected on April 9 and on April 19 were examined by the method of Hoffman and Ficker[4] and by plating on Endo's medium for the presence of the typhoid bacillus. The results were negative. The failure to find the typhoid bacillus in the water was, of course, evidence neither for nor against the presence of such organisms in this water at the time the infection was distributed.

Measures Taken to Suppress the Outbreak.—All the evidence seemed to point to the water-supply obtained from the creek as the immediate source of the infection which had caused the outbreak. The infection in the water may have come from the discharges of the typhoid fever patient or of a bacillus-carrier on the water shed. The following recommendations were made with a view of eliminating the creek water as the primary source of the infection and also to prevent the spread of the infection from such secondary sources as had arisen or might arise:

1. Water.—To discontinue immediately the use of water from the suspected creek unless it could be surely and thoroughly boiled previous to use for any purpose. To make arrangements as rapidly as possible for permanently abandoning the creek as a source of water-supply and to pipe the water directly from the spring to the seminary. Before again using the tanks and pipes through which the creek water had been distributed, to scald them out thoroughly with boiling water.

2. Milk.—To pasteurize all milk used in the seminary.

3. Possible Typhoid Patients.—To isolate immediately all persons becoming ill with symptoms suggesting the possibility of typhoid fever, and to disinfect their excreta thoroughly.

4. Recovered Typhoid Patients.—To have bacteriologic examinations made of the stools and urine of the persons who had had typhoid fever to determine their freedom from infection before permitting the return of such persons from hospital or home to the seminary.

5. General Precautions.—To exercise special care in disposing of sewage and garbage; to flush out the sewerage system with a strong solution of crude carbolic acid; to protect the food-supplies from flies and other insects, etc.

6. To extend the Easter holidays until April 27, so that the improvements could be made before the majority of the students returned.

Result of Carrying Out Preventive Measures.—These recommendations were made on April 7, the day of my first visit to the seminary. They were concurred in by the Maryland State Board of Health and were carried out by the seminary officials thoroughly and as rapidly as possible. The water from the creek was shut off on April 8 and the last patient to contract typhoid fever in the course of the outbreak developed definite symptoms on April 21, just thirteen days later.

---

[4] Hoffman, W., and Ficker, M.: Neue Methoden des Nachweiss von Typhusbacillen, Hyg. Rundschau, 1904, xiv, 1.

A cement basin has been installed immediately below the springs, and into this the water is piped directly from the springs. Each of the springs is cement-walled. The water from the cement basin is conveyed by an iron pipe to the seminary, a distance of about half a mile.

The school term reopened on April 27 and all the students, with the exception of thirty or forty, returned to the seminary. Under the improved conditions all have remained well.

This outbreak strikingly illustrates (1) the comparative ease with which the problem of a local typhoid outbreak may be solved by careful epidemiologic studies, and (2) the readiness with which such an outbreak may be checked when the local authorities have, and exercise, the power to carry out the proper preventive measures.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. DUTTON, STONE AND LUMSDEN

Dr. W. H. Welch, Baltimore: I should like to emphasize the importance of such prolonged, thorough, intensive investigations of the epidemiology of typhoid fever as those reported by the commission, of which Dr. Lumsden is a member, concerning the origin and prevalence of typhoid fever in the District of Columbia in 1906 and 1907. The report of the commission, consisting of Drs. Reed, Vaughan and Shakespeare, appointed to investigate the typhoid fever so appallingly prevalent in our camps during the Spanish-American War aroused attention to the importance of contact and of other sources of infection than the water in the spread of this disease, and the painstaking study of the typhoid fever of the city of Washington has still further emphasized the lesson that in the past we have often been too hasty in attributing the epidemic prevalence of typhoid exclusively to the drinking-water. The experience of Washington is particularly instructive, inasmuch as it was generally assumed before the introduction of central sand filtration in the latter part of 1905 that the Potomac River water was contaminated and was the source of the large amount of typhoid in that city. Despite an apparently admirable system of filtration, the amount of typhoid fever continued high during the summer months of 1906 and to a less extent of 1907. The evidence is strong, even if not absolutely convincing, that the drinking water at present plays no important part in the conveyance of typhoid fever in Washington, and the probability is that it never has been a significant factor there in propagating the disease, despite the almost universal professional opinion to the contrary in past years.

The experience in Washington is probably not exceptional, and it indicates the need of much more careful and detailed study of the conditions determining the occurrence of typhoid in American cities than has hitherto been customary. We should not make the drinking-water responsible for the disease without conclusive evidence. Of course, in many instances such evidence has been presented, and there seems no doubt that a large amount of the typhoid of Pittsburg, Philadelphia and some other cities is water-borne.

Although contaminated milk as a source of infection has long been known, the importance of this factor is not, I think, as yet sufficiently realized. Hitherto attention has been especially directed to explosive outbreaks occurring in the route of particular milk dealers, but there is evidence that the milk may be responsible for not a small percentage of the class of cases hitherto deemed explicable only on the assumption of a water-borne infection, that is, of the scattered and more or less uniformly distributed cases in a city, where the relation to the milk supply is not so immediately apparent. We need protection from the many and peculiar dangers of infection from the white streams of milk which course through our cities quite as much as from the risks of contaminated water. Recent investigations have brought to the front with ever-increasing force contact or the more or less direct conveyance of the typhoid bacillus from person to person as an important mode of propagation of this disease. It is certainly disturbing to learn that the human carriers and distributors of the bacillus are not merely patients in the febrile stage of the disease but are also those incubating the disease as well as persons during convalescence or after recovery, it may be even individuals in health without a history of a previous attack of the fever. It is apparent that the occurrence of multiple cases of typhoid in a household and the demonstration of contact with a typhoid patient afford no accurate measure of the extent of danger from contact, and that the determination of the rôle played by this factor in spreading the disease is often a matter of great difficulty and requires unusually patient and careful search. Under these circumstances it is significant that about 19 per cent. of the typhoid cases in Washington in the summer of 1907 were attributed to contact. In considering the manifold possibilities of conveyance of typhoid germs we should not lose sight of the fact that the primary source of the bacilli is always from human beings, and that every effort should be made to prevent the escape of living typhoid germs from this source into the various vehicles of contagion. In conclusion, I would urge the need for other cities of such painstaking studies by skilled investigators of the modes of conveyance of typhoid fever as those conducted during the past two years in the city of Washington, some of the results of which have been presented to us by Dr. Lumsden.

General George M. Sternberg, U. S. Army: Dr. Lumsden did not refer to one condition in Washington which I think accounts for many of the unexplained cases. In Washington we have a very good water supply and a very good system of sewers, but the sewer system is not complete. We still have a large number of box privies in the alleys and in out-of-the-way places. We have a large colored population living in insanitary surroundings. Many of these colored people are scattered during the summer months at seaside resorts. Some of them no doubt after their return develop typhoid. I doubt whether Dr. Lumsden has been able to keep track of all of these important cases in the alleys of the city. We have a good health department but, unfortunately, not a sufficient number of inspectors. Some of the unexplained cases, I believe, are due to the carrying of infectious material by flies from the insanitary alley houses and out-houses often to the better houses which have sewer connections, and are located on streets and avenues, in the vicinity of the hidden alleys. The fly was not referred to by Dr. Lumsden but it was referred to by the first speaker. It seems that our sad experience during the Spanish-American War was necessary to convince the profession in this country of the rôle of the fly in the propagation of typhoid fever. I was convinced of this some years before the Spanish-American War, and in April, 1898, I issued a circular to medical officers of the army pointing out the dangers from insanitary camps, and especially calling attention to the danger of the transmission of typhoid fever by flies. The reader of the first paper seems to have made the discovery for himself. I think perhaps my official circulars were not read so extensively as they might have been, although most of our regular medical officers of experience were well informed on the subject, but when a lot of undisciplined troops are thrown into unprepared camps with insufficient medical officers, the result appears to be inevitable. Even when the chief surgeon is an officer of experience, he finds himself unable to cope with the situation. I fear that we might have the same result if undisciplined troops were again thrown into unprepared camps in preparation for an unexpected war. Now the remedy for this condition of affairs is proper training of volunteer troops, a thoroughly organized medical department, the prompt removal of febrile cases from the camp, and disposal of excreta by cremation whenever practicable. With a moving camp this may not be practicable, but with a moving camp there is less danger. This is one reason why the Japanese troops suffered little from camp diseases during the recent war with Russia. In the Spanish-American War our troops were assembled in camps where they expected to remain but a short time, but the majority of them were never called on to go to Cuba and remained in the camps, awaiting orders, until the camp site was thoroughly infected. One of my recommendations made at the close of the Spanish-American War was that we should have permanent camps with sewers and a pure water supply, and everything necessary for the assembling of troops in case of emergency. So far as I know, this recommendation has not yet been acted on and I fear that if we had another war and a large number of troops were called out the lessons of the Spanish-American War might have to be relearned by the officers, both of the line and of the medical department.

Dr. Henry B. Hemenway, Evanston, Ill.: The greatest obstacle to progress in the control of typhoid has been the early recognition that sometimes typhoid was spread by water. It is familiarly called a water-borne disease. It has been impressed on me very emphatically, of late, that milk is far more liable to give the disease than is water. The typhoid germ, if I am not mistaken, does not thrive in water. In water it is a weakly germ, which cannot so readily multiply; but in milk it may multiply under exactly the same conditions, because it gets more nutriment. The great problem to-day seems to be the control of what is familiarly called the typhoid bacillus-carriers. That is a problem on more than one account. In the first place, a large number of these individuals are not suspected of being bacilli-carriers. There has been no systematic effort on the part of health departments to keep track of every typhoid case until it is known that the patient no longer excretes the typhoid germ. I can recognize the fact that it would be a hardship on the community, and especially upon the individual, if every typhoid patient were kept, as we might say, in quarantine, using that word even in a very broad sense; but it seems to me that certain laws should be passed which would give a supervision of all bacilli-carriers. Diphtheria presents a similar problem. I had an instance within the last six months; the bacillus-carrier, a woman perfectly well and strong, absolutely objected to being restricted. She happened to be a diphtheria carrier. A number of cases of diphtheria were shown in a certain territory occasionally cropping out; and the thing was to find where the infection came from. Finally, it incidentally came to the knowledge of some that there was a particular fruit peddler going through that territory who himself was well but had had a case in his family which was suspiciously like diphtheria. The typhoid carrier is particularly dangerous whenever he comes in contact with any food which others will eat without further cooking. The typhoid carrier should by law be restricted from any employment on milk farms; he should be restricted from employment in a bakery, or in a grocery, or in any such place.

Dr. Juan Guiteras, Havana, Cuba: I have had no special experience with typhoid fever from the point of view of the public health officer. We have little typhoid fever in Havana. Our water supply is excellent, coming direct from abundant springs. The milk used in Cuba is always boiled. No raw milk is ever drunk in Cuba. Perhaps for those two reasons typhoid fever is limited there. The tracing of contact relations in the few cases that we do have in Havana is usually not difficult.

Dr. A. C. Abbott, Philadelphia: Coming from a community in which the average incidences of typhoid fever has been for years approximately 6,000 cases annually, it is not unlikely that some at least of our experiences may prove to be of service. In the beginning, I should like to subscribe to that which has already beeen said by Dr. Welch concerning the instructive work of the Washington board of which Dr. Lumsden is an active member. It has brought out in an impressive manner the complicated nature of the problem of typhoid fever as it effects a community, and has left no doubt in the minds of those familiar with it that no stone should be left unturned in seeking for the causes of endemicity of typhoid fever. It also demonstrates that conclusions drawn for one community may not of necessity be applicable to others. You have heard what has been said concerning Washington. In Philadelphia there is no reasonable room for doubt that our principal trouble lay in the filthy, grossly polluted drinking-water with which our city until very recently was supplied. With the introduction of proper methods of purifying that water, the occurrence of typhoid fever immediately lessened by about 80 per cent., and we believe that with the continuance of the purifying methods and the further extension of the system that this reduction will be still greater reduced. There is no doubt that many cases in the city arise from the use of specifically infected milk, but I would hesitate to form an estimate of the proportion of these cases, for it would be nothing more nor less than guess work. On several occasions we have, it is true, succeeded in tracing to their origins some isolated outbreaks of the fever due to contaminated milk. Two of these are so instructive and worked out with such mathematical percision that I am tempted to relate their main points:

One outbreak occurred in one of the lower wards of the city and involved over fifty persons. Without entering into the details, it will suffice to say that on investigation the milk purchased by these individuals was found to have come from a farm on which about three or four weeks prior to the outbreak there had been in a family of seven, five cases of typhoid fever, the two remaining members, the wife and a little daughter, having charge not only of the patients but likewise preparing the milk for market. The bedpans used by the patients were washed on the back porch immediately over the spring used for rinsing the milk cans. The next outbreak involved a number of students at one of the colleges in Philadelphia. In this instance we found the milk being supplied to have been produced on a farm where inspection showed everything to be in a satisfactory condition. It was, however, handled by a middleman and in looking into affairs at his place we found that the milk was being bottled from the cans by means of a rubber syphon. His two sons sucked the milk up from the can with an ordinary piece of rubber tubing and allowed it to flow into the bottle. One of these sons within a day or two was taken to the hospital ill with typhoid fever, and in less than a week the second was also sent to the hospital with the same disease. That experiences of this kind are to be had in every community I have no doubt.

With the contact cases we have a much more difficult problem. Of course, the obvious contacts we exclude from our consideration but that there is a subtle dissemination of the disease through ways of contact not obvious I have no doubt whatever.

A great difficulty in satisfactorily tracing out completely the dissemination of this disease lies in the almost impossibility of securing uniformly correct histories. It is astonishing how few apparently intelligent people can answer no questions in such a way as to aid you. Many do not seem to have the least recollection of where they have been or what they have done during the incubation period of the disease. Others make statements that are intentionally misleading, I am sure.

Another difficulty that is common to most communties is incorrect diagnosis. We have repeatedly had reports come to our office of persons having typhoid fever at such and such an address. Often in less than a week from the onset of the disease these persons are attending to their ordinary avocations.

Until there is some concerted action concerning the control of water courses the municipal problem of typhoid fever is going to be very largely a water problem.

It is needless for me to mention the variety of other ways in which the disease may be disseminated, such as by insects, by vegetables grown in land fertilized with human manure, by shell-fish taken from polluted waters, etc.

Dr. Liston H. Montgomery, Chicago: Perhaps raw oysters and other shell-fish have something to do with the dissemination of typhoid fever in the cities on the coast. In Chicago the people cannot all afford these luxuries. It is well known that the dissemination of typhoid is due to the house-fly and the fruit, or pomace, fly, roaches, etc. Weeks ago our Commissioner of Health issued a bulletin instructing housewives on the necessity of placing in windows wire screens, so as to prevent flies from entering the house and contaminating the food. In some of the cities, as I understand it, active war has already been begun for the extermination of the house-fly. Bacteriologists who have captured flies in the houses stained these insects, as I understand it, with a brilliant dye and released them, watching the flies afterward by following them and seeing that they reveled in filth boxes, garbage, etc. Later these same flies returned to the houses where they were previously captured and stained; then, before they had time to contaminate food, they were recaptured and their excreta, or contents of their alimentary tract, were investigated and were found to contain the bacteria, not only of typhoid, but of various other diseases.

In one of the larger towns in the East a householder, having recovered from typhoid fever proved to have been contracted, I understand, on account of the polluted stream that went through the town, instituted a lawsuit against the town and, I believe, recovered damages by judgment.

DR. SENECA EGBERT, Philadelphia: One other source of infection has not been mentioned to-day, and I am rather surprised thereat. It is not a proved source, but it seems to me a very possible one. I refer to celery, lettuce and other articles of food which come to us in the fresh, green state. I have in mind three instances which seemed to me to help make that a possibility. One case was that of the small child of one of my colleagues, in whose home I can vouch for extraordinary care as to typhoid infection. The little girl had a serious case of typhoid; and in the minds of her parents the only thing that could have caused it was celery, of which she was very fond and which they used very largely in the household.

Some years ago members of one of the improvement associations in the northern part of Philadelphia came to me and asked my opinion as to the use of night-soil from old privy vaults on the truck farms in their neighborhood. They declared it a common practice of these farmers to use night soil on these farms. I saw an Italian picking watercress from a little stream which was close to the ends of the ties of the railroad track and which could readily have been polluted and infected by a typhoid carrier on a passenger train. So it seems to me entirely possible that a number of cases may occur in this way through infection from such articles of food as are consumed in the fresh, green state and which cannot, so far as I know, be sterilized and made free of the germ, once they are contaminated.

I am glad to testify that Dr. Abbott has been one of the factors in Philadelphia which have brought about that elimination of a large proportion of our typhoid cases and which we are very glad to have eliminated. The sources of the others may continue to puzzle us for some time to come, but must eventually be discovered and eliminated.

This problem is a very complex one, demanding the attention of every sanitarian. For a long time I have felt that it is just as important a problem as tuberculosis; while the incidence and the death rate from typhoid may not be so high as in the case of tuberculosis, I think a crusade against the former carried on with the same vigor and the same widespread effort the country over as that against the latter would result in a much greater diminution in death rate and incidence than the tuberculosis crusade can possibly hope to achieve in anything like the near future.

DR. J. N. HURTY, Indianapolis: Other theoretical sources, and we now think practical sources, of typhoid fever, are public lunch wagons, public fruit stands and candy wagons. My attention was directed to this by a newspaper man. A reporter was taken ill with typhoid fever; and the man who made his rounds, afterward talking on the subject to me, said: "I don't know where he could have gotten it; unless from one of those lunch wagons." Then a policeman who frequently patronized the same lunch wagon was attacked with typhoid. Investigation showed that the lunch man had typhoid in his family; so, of course, there was the source, and it is comparable to the restaurant source.

In regard to the spread of typhoid fever by contact: The Indiana Soldiers' Home at Lafayettte is beautifully situated. The sanitation is very good. There was no typhoid there—had not been for years. The commandant's son came home with typhoid from school. The chief physician of the institution attended him, and presently the disease spread all over the institution. There were 65 cases and 1 death. After a thorough investigation showing the deep well-water to be pure, the sewage perfect, and all that, we found that the physician spread the infection all through that institution. He came down with it himself and was very ill—so ill that he was delirious while the investigation was being made. We asked him what precautions he took after he handled the patient; what precautions he took in regard to washing his hands, and he said he did not take any. "Did you wash your hands?" "Well, sometimes I did and sometimes I did not." In this instance 65 patients were infected by the physician himself; not all of them, of course, but he started the infection. So a physician may be a distributing agent.

DR. HENRY B. HEMENWAY, Evanston, Ill.: I have long been accustomed to use a little coverette on my thermometer, so that the thermometer never touches the patient. It seems to me that is a precaution that might well be used in such cases.

DR. A. W. FREEMAN, Richmond, Va.: We have had in Richmond, and later in Virginia at large, an interesting experience with typhoid. The Richmond investigation was begun independently of the Washington work, and the results were in perfect accord with those arrived at in Washington. The parallelism between the typhoid rates of the two cities, as has been pointed out elsewhere, is remarkable. We were able, also, to account for about the same percentage of cases, leaving the larger number of cases without explanation. In July, 1908, the newly reorganized state department of health began a similar investigation of the small, local outbreaks in Virginia, believing that these, offering less complicated situations than the outbreaks prevailing in the larger cities, would throw more light on the problem. The results of this investigation were varied. Of about thirty outbreaks investigated a few were apparently caused by water, but by far the larger number of cases in the smaller towns could be traced to the carrying of the infection from house to house by food, or by the visits of neighbors entering the sick-room. Even the most casual contact might, apparently, be responsible for the spread of the disease.

This year we hope to investigate the true rural typhoid; typhoid on the farm, where the whole process of spread can be seen plainly. On the average Virginia farm you can follow the movements of every member of the family for weeks and even months prior to the outbreak, and we have already followed out a number of these cases, where the disease could be traced from farm to farm, over long distances. We believe that this type of the disease offers a particularly inviting field for investigation. We believe strongly in the contact idea as applied to typhoid in Virginia. We have no opinions to offer as to typhoid in any other locality, but so far as our present experience goes we do not believe the farm well to be responsible for any great number of cases. It is the contact of the well person with the patient that results in the spread of the disease in Virginia.

DR. F. F. RUSSELL, U. S. Army: There is another way to prevent typhoid fever besides tracing down the source of infection and destroying that source, and that is, by vaccination, or inoculation or immunization of a body of men. While this is not a practicable matter for civil life within any large limits, it is within the military service, and the surgeon-general of the army has now started to immunize large bodies of troops against typhoid. The British and German campaigns against typhoid fever (which are conducted as our own, with the idea of preventing infection from every possible source and without neglecting any other means which will help us in stamping out typhoid) have shown that vaccination against typhoid undoubtedly does protect and that it protects for a considerable length of time. The figures of the British (which have recently been published and which have been mentioned by Dr. Stone) show very roughly that among those men who have been vaccinated there is only one case of typhoid to every ten cases among men equally exposed who have not been vaccinated. Now that result is sufficient to encourage us in the use of vaccination among all persons who are to be exposed to typhoid. Going into a camp is equivalent to going into an endemic area, for typhoid prevails everywhere in the United States; and we cannot organize a camp or assemble any large number of men without having typhoid introduced inside of three weeks. The disease will spread by contact, almost altogether by contact, and contact in a camp is much more intimate than in civil life, so that the dangers which are present everywhere are present in a much greater degree in camp. We feel that not only must we provide pure water and pure food, and destroy the excreta, etc., of everyone, but we must also vaccinate everyone who can be persuaded to take it as an additional means of reducing the morbidity and mortality from this disease.

Dr. James B. Bullitt, University, Miss.: In my town (population 2,500), cisterns, shallow wells and privies were in use until about ten years ago. On the installation of a sewerage system and of a water supply from artesian wells, typhoid, which had been fearfully prevalent, practically disappeared. There is one block, however, occupied for the most part by the better class of people, where the configuration of the ground prevented junction with the main sewers. A short sewer was therefore laid emptying into a little ravine only a few rods away. The water supply is the same as for the rest of the town. Here several cases of typhoid have occurred every year, though the rest of the town has remained practically free. As there have been several intervals of eight or ten months between consecutive cases, it seems unlikely that each crop has developed from those immediately preceding. It is my opinion that some bacillus-carrier, whom we have been unable to identify, lives on that street and intermittently infects the ravine, from which doubtless flies and other insects carry the infection to the neighboring houses.

Dr. Gardner T. Swartz, Providence, R. I.: In Providence, when an epidemic breaks out in a quarter, the health officer is called on to put his finger on the source; if he cannot he is not a master and cannot hold his position. The public is now becoming informed of these matters and the possibilities that we have of determining the various sources of this disease. We must encourage our departments, both state and national, in the promulgation of this investigation work, and urge that the laboratories must be so situated, and of such convenient distances, that we shall be able to utilize them for carrying out the study of this disease, concerning which on many occasions we must acknowledge our impotence.

Dr. Martin Friedrich, Cleveland, Ohio: These discoveries of new carriers of typhoid fever germs are not only interesting but of great importance but let us remember that in the main typhoid fever is a water-borne disease.

Dr. H. M. Bracken, St. Paul, Minn.: We had a beautiful opportunity to study typhoid in Minnesota in a little town where we told them they were going to have it; and we got the first case. A short time ago my attention was directed to a farm where the residents were man and wife, and where every employee for the last seven or eight years who has come onto that farm has had typhoid fever. I asked if either of the members of the family had had the disease and I was told by the physician no; but when we sent someone to find out, we found that the wife had had typhoid several years ago.

Dr. W. Forest Dutton, Walkers Mills, Pa.: When I prepared this paper I expected critical discussion, and earnestly desired it, for my own personal edification more than anything else. The technic was not different from that used by bacteriologists. Precautions were taken to eliminate other than the *Bacillus typhosus* of Eberth. When I say typhoid, I mean, distinctly and absolutely, the bacillus of Eberth and not paratyphoid, colon, or the paracolon bacillus nor intermediate species. I used culture media most suitable to the individual case. It is truly a difficult task requiring ofttimes months to secure positive results. It has been known for years that typhoid bacilli reach the blood through other than ordinary channels. In the first two weeks of typhoid there is a marked blood infection; the bacilli occur in the tissues in clumps, and the roseolæ contain bacilli. Bacilli are frequently found in urine, feces, bile, and pus, years after primary infection. Thence, it can easily be inferred how the infection is accessible to the insects referred to in my paper. The proofs that have been furnished by Grünbaum and Sanarelli prove the specific character of typhoid.

In reference to typhoid commissions, I would say that a great deal has been accomplished by their efforts, yet salient etiologic factors are frequently overlooked. A general survey is made of epidemic and endemic outbreaks of typhoid, and general data are accumulated. The fact remains, however, that a commission cannot study individual cases as affecting rural districts, and this, perhaps, accounts for failure to learn the source of infection.

In closing, I should like to say that vaccination against typhoid will, when the method is perfected, prove one of the greatest boons to the human race, second only to vaccination against smallpox.

Dr. L. L. Lumsden, Washington, D. C.: It is a great pleasure to see such a keen interest taken in the typhoid problem. The many valuable suggestions made in the course of the discussion I am sure will aid us in our future work in Washington. At the beginning of our studies in Washington we suspected that there might be many cases of typhoid which were not reported and which might constitute some of the undiscovered links in the chain of transmission of the infection by contact. In the summer of 1908 we conducted a house-to-house canvass in 32 city blocks having a population of about 6,000. The results of this canvass incline us to believe that in Washington more cases of typhoid are reported than exist in a clinical sense.

As Dr. Welch remarked, I probably did not sufficiently emphasize the milk problem. The pronounced milk outbreaks in Washington may be regarded somewhat as acute exacerbations of a chronic affection. A number of scattering cases doubtless are due to milk-borne infection which cannot be traced. In our reports charts are presented which show the occurrence of typhoid cases among customers of different dairymen proportionate to amount of milk sold. One dairyman who sterilizes bottles and cans and pasteurizes milk has had among his customers a consistently low typhoid rate. This is significant and perhaps indicates what would be the result of the pasteurization of Washington's general milk supply.

There are now in the District of Columbia only about 3,000 privies. We expect to find a higher rate of prevalence of typhoid in the sections largely provided with privies; but we were disappointed and we have not been able to say as harsh things about privies as we had hoped. It is true that there are in Washington insanitary alleys having a crowded negro population, but we have found that the prevalence of typhoid in these alleys is no greater than in the better sections of the city. We have given considerable attention to flies. No preponderance of cases has been found among persons living in unscreened houses and among those whose occupations exposed them unduly to flies. Last summer Dr. L. O. Howard, at our request, made a study to determine the seasonal abundance of flies in Washington. The lack of parallelism between the curve showing the seasonal abundance of flies and that showing the seasonal prevalence of typhoid opposes the view that flies are a major factor in the transmission of typhoid infection in Washington.

It is encouraging to hear from Dr. Guiteras that there is very little typhoid in Havana. Havana is distinctly a tropical city, having the year round about the same climate that Washington has during the summer, Washington's typhoid season. It seems that, regardless of climate, localities having good water, good milk, good sewage disposal and in which typhoid patients are properly cared for have as a rule little or no typhoid.

Publicity in Tuberculosis.—Publicity through the press is being utilized with good effect in the fight against tuberculosis by the Board of Health of Salem, Mass. A series of articles has been prepared for insertion in the newspapers which aim to give information that will be of benefit to the people in general. The objects of the articles are to show the great frequency of tuberculosis and the importance of infection, bad habits and insanitary surroundings as compared with heredity, to arouse public officials to a sense of duty, to instruct the well as much as the sick, and paint the consumptive's future as bright as possible, avoiding extreme opinions and interference with the proper field of the physician. The articles are supplemented by a skillfully managed question box in which many of the popular fallacies regarding the disease and plausible objections to the statements made in the articles are corrected and refuted. The method of the Salem board is worthy of the attention of other health authorities and has received the commendation of a considerable number. Such articles must be carefully managed to avoid exciting undue alarm, but the hope of cure held out to sufferers from the disease and the sensible stand taken in these articles as to danger from contagion is likely to avoid such a result.

A CONVENIENT METHOD FOR DETERMINING CALORIC VALUES OF FORMULAS BASED ON PERCENTAGE FEEDING OF INFANTS *

HENRY I. BOWDITCH, M.D.
BOSTON

At present there are two schools in the pediatric world more or less opposed to each other on the subject of infant feeding. The German school almost universally supports the caloric, while the American school largely upholds the percentage system. It is apparent to all that each school must have its good points when supported by such representative men as Heubner, Camerer, Rotch, and Holt.

While one pediatrician using the percentage system of feeding occasionally calculates the caloric value of what he prescribes—not a rare procedure — another man can be seen following the German idea, who calculates regularly the calories considered essential, but seldom, if ever, knows what kind of percentage strength of food he is giving. Both schools support their side of the question stoutly and each seems to me rather slow to see any good in the other. If these can be combined, the good of each will strengthen the value of the other. Heubner, Camerer and others of their school have said that they have successfully fed children by using simple dilutions of milk, letting the caloric value of the food not exceed from 100 to 120 calories per kilogram per body weight and gradually reducing this to 80 calories at the end of the first year. Granting that Heubner's caloric value of milks, diluted to suit the digestion, is correct and is important for successful feeding, why is it not important also from a scientific as well as a practical point of view to have these same dilutions calculated in percentages of fat, sugar and proteid?

TABLE OF CALORIC VALUES USED IN INFANT FEEDING

(Values are estimated according to percentage strength of constituent and the amount of food.)

Percentages of fat, carbohydrates, proteids, water, solids, etc., to a certain extent, are, we know, taken into consideration when feeding delicate digestions among adults. Why is it, then, not far more important to consider the same things when using food in the feeding of infants? We hear from Czerny, Camerer, Salge, Holt, and others that fats are not easily borne by the child and are frequently seen to be the cause of acute and chronic indigestion. If this is true, and I am fairly convinced of the fact, a knowledge of the percentages of ingredients in the milk formulas, etc., will be of great practical value.

I shall not enter into the much discussed fields of the digestibility of fats, sugars and proteids for infants, or their management in home modification or laboratory prescriptions. I merely wish to urge a more constant trial of the use of the two systems, using them in the proper relation one to the other. The percentage system, no matter how calculated, prevents, if properly used, the over-feeding of fat, and holds one within the conservative limits of sugar and proteid, while the caloric value of these same percentages prevents one from overcharging the intestine and putting too much work on the digestion of the infant.

My object in writing this paper is, first, to urge a more thorough trial of these combined methods, and, second, to offer to the medical profession a plan, other than the ordinary, as a possible aid in computing the calories of any formula of infant feeding based on the percentage system.

This plan depends on a table of caloric values for the different percentages of fat, sugar and proteid used in infant feeding. These values are calculated for each gradual increase of strength in percentage, and of the quantity of food. These same values are placed side by

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

side in columns and rows, so that the columns represent values of different percentage ingredients of the same quantity, while the rows represent the same per cent. strength of ingredient of different quantities. (For the former read up and down, for the latter read horizontally.) The fats differing in caloric value from the sugars or proteids (9.3 Cal. to 4.1 Cal.) are worked out by themselves. The sugars and proteids of similar energy power (4.1 Cal.) are estimated together.

The increase is 0.25 per cent., as is shown in the left-hand column. This is used throughout the table for fats, sugars and proteids, it being practically about the smallest and at the same time the most exact per cent. possible to be used in home modification and laboratory formulas. In the combined sugar and proteid values the strength will be seen to increase above 4 per cent. by 0.5. The limits of percentage for fat, sugar and proteid are taken from the general reading and practice of American and foreign pediatrists. The fats are estimated from 0.25 to 4 per cent., the 0.25 per cent. representing the lowest practical strength, while the 4 per cent. represents the usual strength in "whole milk" of Holstein and Ayrshire cattle, which is further generally agreed to be the safety point above which tolerance and indigestion, due to fats, seem to appear most often. The upper limit of sugar and proteid is that which is generally accepted as essential for ordinary use, that is, 7 per cent. in sugars and 3.5 per cent. for proteids.

The increase in quantity is shown in the two top rows of the table. Here, reading from left to right in the second row, are shown the gradual quantitative increase of food constituents from 1 to 10 cubic centimeters. The decimal system, although not much used in this country, is rapidly advancing. It has seemed to me the most natural and the easiest one to use when dealing with percentages. By merely changing the point to the right one, two or three places in any column the value of ten, one hundred and one thousand times the amount of the ingredient can be instantly seen (i. e., take "3 c.c." column; by moving the point one place, we have the value of 30 c.c., two places, the value of 300 c.c., and with three places, the value of 3,000 c.c.). For those who wish to calculate in ounces, the top row of figures has been added. Here we rely on the fact that one ounce practically equals 30 cubic centimeters, two ounces 60 cubic centimeters, and three ounces 90 cubic centimeters. With this knowledge, the values of one, two and three ounces can be estimated by following down the "3, 6 and 9 c.c." columns and changing the decimal point one place. For 10, 20 and 30 ounces merely change the point two places.

The method for computing the table is simple. The energy values for one cubic centimeter of 0.25 per cent. of fat, sugar and proteid are calculated. The resulting figures are used as factors or bases, whence by mere addition or multiplication all other values are easily worked out. One gram of fat possesses 9.3 calories of energy, and is practically equivalent to one cubic centimeter of fat; then one cubic centimeter of fat has 9.3 calories of energy. For example, if one cubic centimeter of 0.25 per cent. fat has 0.02325 calories, then 2 cubic centimeters will have just twice that amount, or 0.04650 calories; and, again, if one cubic centimeter of 0.25 per cent. fat has 0.2325 calories, then one cubic centimter of 0.50 per cent. fat will have twice the number of calories as are in one cubic centimeter of 0.25 per cent.

THE METHOD OF USE

When using percentages in feeding, the caloric value is ordinarily calculated by multiplication of the percentage of fat, sugar or proteid by the respective value of one gram of each ingredient, and then by the total amount of food in the twenty-four hours. To complete this problem, these three values must be added together to procure the actual daily energy of the food. For example:

Formula: Fat, 3 per cent.; sugar, 6 per cent.; proteid, 1 per cent. Total amount, 300 c.c.

Three hundred cubic centimeters of 3 per cent. fat, 300 x .03 (3%) x 9.3 cal. (energy value of 1 c.c. fat) gives 83.7 calories.

Three hundred cubic centimeters of 6 per cent. sugar, 300 x .06 (6%) x 4.1 calories (energy value of 1 c.c. sugar) gives 73.8 calories.

Three hundred cubic centimeters, of 1 per cent. proteid, 300 x .01 (1%) x 4.1 calories (energy value of 1 c.c. proteid) gives 12.3 calories.

Total, 169.8 calories.

This requires two multiplications in each ingredient, or a total of six. By referring to the table it is seen that by knowing the percentage of fat, sugar and proteid in the food, as well as the total amount, these same values are quickly found and the multiplications are done away with. The addition in both methods is and always will be necessary.

Read down the respective percentage column until the desired percentage is found, follow this row until the amount is reached, then read. Add these values and the total caloric value of the food results.

Formula: Fat, 3 per cent.; sugar, 6 per cent.; proteid, 1 per cent. Total amount, 300 c.c.

Look down the percentage column until 3 per cent. is reached, read now to the right until "3 c.c." column is seen, as the total amount is 300 c.c.; move the decimal point two places, and we have 83.7 calories for 300 c.c. of 3 per cent. fat. This same process is done in the percentage columns of sugar and proteid and we quickly find the calories of sugar to be 73.8 and those of proteid to be 12.3.

Variations in the above example appear when the total amount becomes an uneven quantity, 330 cubic centimeters, or 440 cubic centimeters. Here the problem is slightly increased. We find the value for 300 cubic centimeters, and for 30 cubic centimeters, by merely changing the decimal point; the addition of these two gives the total. When the total quantity is in ounces, we use the ounce columns and proceed as if using cubic centimeters, changing the point as occasion demands, and when necessary multiples of the same (i. e., for 6 ounces, twice the value of 3 ounces, for 4 twice that for 2 ounces, etc.).

All tables and formulas in infant feeding only add trouble to this already most complicated subject, unless they fulfill certain requirements. The method of formation must be clearly understood and the method of using the same, while both must be simple. Unless such tests can be applied to any such scheme, difficulty arises, and the table or formula is worse than useless. I have attempted to show as shortly and as concisely as possible how this plan was worked out and is used. It is simple, I think, to understand and to use; therefore, I hope that it may be of some service to the profession and possibly aid in the fusion of the two theories of the foreign and American schools.

Tracheotomy in Cancer of Larynx.—Tracheotomy cannot be considered as a curative operation. It serves only to relieve the stenosis of the larynx caused by the cancer, or comes into play as a preliminary to the radical external operation.—O. Chiari, in *Annals of Otology, Rhinology and Laryngology.*

HEUBNER'S SYSTEM OF INFANT FEEDING EXPRESSED IN CALORIES AND ENERGY UNITS*

E. LACKNER, M.D.
CHICAGO

No food, no growth.

After the fourth week of life in a qualitative, and after the sixth week in a quantitative manner, a certain normal feeding has been established for the child which allows of an average estimation in quantity and quality of food taken. The single and daily feedings of the infant will closely approximate the averages fixed.

After the sixth week the child requires from 600 to 900 (from 20 to 30 oz.) grammes daily and after the fourth month from 1,000 to 1,100 grammes (33 to 36 oz.); these amounts are seldom exceeded. These figures have been established by weighing a large number of children daily for months and represent average values. According to the observations of Dr. Feer the amount of food taken daily by one individual infant varies greatly; in this the child resembles an adult. These daily variations in feeding of infants must be remembered when we take up artificial feedings. The number of daily feedings in the cases observed and controlled were not frequent. The first three or four weeks of life the infant was fed every two hours; after this from six to seven times daily. After the fourth month six daily feedings were given, and in many cases only five.

The quantity taken at each meal varies from 50 to 200 (1⅔ to 6½ oz.) grammes. The time taken for a meal varies in individual cases from fifteen minutes to one-half hour. After the third week there is very little variation in the chemical quality of the mother's milk. The constituents are not so fixed as in a mineral water; fat varies greatly at the different feedings. Frequent examinations of milk obtained in sufficient quantity of the same breast, repeated for days, will show a surprising sameness. Further, the examination of milk from many different mothers also agrees so nearly that an average has been established.

In 100 grammes (3 oz.) of mother's milk the infant gets according to the form established:

Proteids.	Fats.	Sugar.	Salts.	Unknown organic substance.
(13½-15 grs.)	(50-60 grs.)	(90-105 grs.)	(2.85 grs.)	(6 grs.)
0.9-1.0%	3.5-4.0%	6.7-7.0%	0.19%	0.6%

When the milk reaches the stomach it is rapidly changed. The casein is precipitated, but, as there is but little casein in mother's milk, the precipitation is fine and flocculent.

Casein and salts remove the acid of stomach secretions and it requires from 1 to 1½ hours before it reappears. According to von Mehring, whenever the intestines are filled up, no more food is allowed to escape the stomach, and thus the bowels are guarded against overflow and overwork.

All foods entering the body are acted on by the infant's organs and are disposed of in various ways. Much of it escapes through urine, fecal matter, exhalations from lungs and perspiration. Some of it, however, is added to the body as an increase. These processes are expressed in terms by Rubner as *Energie-Wechsel* (bodily activity) and *Energie-Bilanz* (increase). All duties performed by the body inclusive of adding to the growth are expressed by the term *Energie*.

The energy of a given food is expressed by the heat given off in its burning. The balance of food remaining in the body can be expressed in calories by deducting the amount lost through fecal matter, urine, etc., from the amount entering the body. Food given can be expressed in calories and is of greater significance than if expressed by weights and measures. It can be stated, *a priori,* that in a healthy infant of a steady, regular growth, for equal units of bodily weight we have equal working power in each individual case.

In this case the introduction of food or energy must be regular and of given quantity. By carefully examining a considerable number of normal thriving infants, being able to control them in every respect, so as to establish a proper basis for calculation, Heubner was enabled to express the energy power of the food required by the infants.

The daily amount of food required by a normal thriving infant expressed in calories per kilo (about two pounds weight) of infant is called energy quotient. A more thorough analysis of these infants showed that from the end of the third week to the end of the sixth month the energy quotient is 100 grammes; that is, for every kilo (2 lbs.) weight we require 100 grammes food (3⅓ oz.).

In the succeeding months to the end of the first year there was a gradual reduction in energy quotients. The amount of work required of the infants simply to preserve life—that is, energy power of the food taken minus the energy power of fecal matter, urine and growth—appears in the first six months to equal 70 calories per kilo weight daily. This has been proved by von Feer, Beuthner, Nordheim, and particularly Schlossmann, through various experiments to be approximately right for the first three months at least. Schlossmann is inclined to place the energy quotient to 110 grammes; this determination is based on milk obtained from wet nurses and reduced to calories. Czerny and Kellar have not succeeded and point out what they consider inaccuracies.

It will require further study and experience to prove whether they are inaccuracies or not. Not only in case of breast-fed infants is the food thus to be expressed, but in artificial feeding, the food can be expressed in calories and by learning the caloric value of the several foods used in artificial feeding we can easily compute or compound a food for an infant.

According to Rubner:

	Calories.
Mother's milk contains in 1 liter (dependent on fat contents)	614-724
Cows' milk, per liter	690
Two-thirds milk, per liter	480
One-half milk, (½) 10% sugar solution, per liter	500
Buttermilk (according to de Jager)	698
Liebig's soup (according to Kellar)	808
Allenburg's milk mixture	546
Asses' milk (Dresden)	502

One needs to know the weight of the infant to determine the quantity of the above foods to be given to satisfy its energy requirements.

An infant weighing 5 kilos would require 500 calories cow's milk; 700 calories to 1 liter. Therefore, we would require 5/7 of 1 liter of cow's milk or buttermilk; 1 liter ⅔ milk; ⅝ liter of Liebig's soup, etc. Of course, the above calculations premise that artificial food is as good as mother's milk. This we know is not so by a good deal.

A high percentage of nitrogenous contents in food for infants is not economical because a low percentage answers all demands. Further, nitrogenous food requires good digestive organs. The different proportions of casein and albumin in cow's milk and mother's milk are well explained in all text-books and require no elucidation here. The differences, however, have greater theoretical value than a practical one. The differentiation and characterization of the several nitrogenous compounds in the organic fluids have not reached that stage which would allow us to come to any definite conclusions.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

What is of greater importance is the presence in mother's milk of substances rich in phosphorus, as nuclein and lecithin, which are not found as well represented in cow's milk. In fact, there are more unknown substances which contain nitrogen in mother's milk than in animal milk.

Based on these chemical differences, as well as on the result of experiments, digesting nitrogenous compounds in test tubes, both of cow's milk and mother's milk, the conclusion was reached by different savants and so promulgated that cow's milk was hard to digest owing to the nitrogenous properties. This doctrine, however, has been disproved by experiments on infants. In fact, it was proved that the nitrogenous compounds, those of cow's milk as well, were easily and thoroughly digested (about 5.5 per cent. loss), and when not made use of in the body were chemically changed and passed in the urine.

This doctrine would not have received so much consideration and been so persistently believed, but the daily experiences seemed to prove it. A child could digest diluted milk quite well, but not whole milk. In whole cow's milk the nitrogenous compounds are far in excess of the same elements in mother's milk, while the fats and sugar are of about the same percentage; therefore, the nitrogenous bodies are the indigestible ones. This conclusion is probably right, but the explanation of the conclusion is interpolated and this is not right. That is, the conclusion is not based on rigid experimentation; it is not proved. Rubner and Heubner were enabled to study carefully the effects of artificial feeding—cow's milk, on two children, a seven months old child and a three months old sickly child—and from their observations and studies obtained a clearer idea of the digestion of nitrogenous compounds. What is the effect on an infant of a nitrogenous diet much richer than a breast-fed child obtains? It does not increase the growth of the child to any appreciable amount, but we have an increased destruction of nitrogenous compounds, and if we continue for some time this rich nitrogenous feeding we influence the metabolism of the body. The increased metabolic processes in the body increases the heat production. This was ascertained in the two children to be from 9 to 15 degrees daily more than in a breast-fed child. This overproduction of heat must be got rid of, and in the children examined it was accomplished through increased perspiration and exhalation from the lungs. This all means increased work for the infants.

The digestion and absorption of this richer food, the destruction and the disposition of the increased heat, all caused extra work for the internal organs without any benefit to the infant, no increase in growth or in repair of worn-out tissue. The increase of albumin in the cells of the body is not accelerated by a too rich nitrogenous diet, but is interfered with.

By continuing this rich nitrogenous diet, or rather, overfeeding, we injure the entire organism. This manifests itself first by loss of appetite. Observation has shown, particularly in delicate children, that it is always better to dilute cow's milk.

This dilution even during the first month of a full term baby does not need to be more than will reduce the proteids of cow's milk to equal the proteids in mother's milk. That is one part of milk and two parts of water. This mixture contains 0.9 to 1.0 per cent. proteids. Of this mixture the same amount is to be given as the child obtains from the breast when nursing, because if more were to be given the reason for diluting would be negatived.

If we were to give two or three times as much of this mixture as the child obtains when nursing we would give two or three times as much proteids and inorganic salts as we had determined, and also an unnecessary amount of water.

During the first month we give of this one-third mixture 400 c.c., at later periods of growth 600 or 700. c.c., in 5 or 6 meals daily if we wish to keep the amount of proteid equal to that of mother's milk.

It is clear, however, that this mixture has not the nutritive value of mother's milk volume for volume, because the non-nitrogenous bodies which are about equal in both fluids normally are reduced two-thirds in cow's milk.

This is the great evil in diluting cow's milk, but one that can not easily be remedied. Milk sugar, of course, can be added to 7 per cent., equal to the amount in mother's milk.

These differences are not the only ones resulting from diluting cow's milk. The organic substances containing phophorus, nuclein and lecithin, which whole cow's milk contains in less quantities than mother's milk, are still further reduced. *The physical properties of this* new mixture will be unfavorably influenced. It has been determined by Hans Köppes that cow's milk, notwithstanding its higher percentage of proteids and inorganic salts, has about the same molecular concentration that mother's milk has. Freezing point and electrical resistance will be disturbed and thus resorption will be unfavorably influenced.

Too great dilutions, 4 or 5 times, will conduct too much water to the system and overflood it. For these reasons it is not best to dilute cow's milk more than absolutely necessary. The highest dilution that physiologic conditions would allow is one part milk to two parts water. One part milk, two parts water, 8 per cent. sugar to keep sugar up to 7 per cent. in 100 parts.

	Proteids.	Fats.	Sugar.	Ashes.
33 parts milk	0.9	1.2	1.5	0.2
66 parts 8 per cent. sugar sol......	. .	. .	4.3	. .
	0.9	1.2	6.8	0.2

400 Calories.

This as a mixture, viewed as an ordinary chemical mixture, resembles mother's milk with the exception of fats. We can, however, increase the volume taken by the child by from 100 to 150 c.c. (from 3 to 5 oz.) over that obtained by nursing to overcome the deficiency in fat.

A simple way would be after the first two to three months to give the one-half mixture, which is as follows:

	Proteids.	Fats.	Sugar.	Ashes.
50 parts milk	1.5	1.8	2.2	0.35
50 parts 10 per cent. sugar sol.....	. .	. .	5.0	. .
	1.5	1.8	7.2	0.35

500 Calories.

This mixture shows an increase of proteids and sugar over mother's milk, but deficiency in fats, and can be given in the same volume as mother's milk of the same period.

Finally, from the third or fourth months we may give the two-thirds mixture; that is, two-thirds milk and one-third water in 100 parts.

	Proteids.	Fats.	Sugar.	Ashes.
66 parts milk	1.8	2.4	3.0	0.47
33 parts 12 per cent sugar sol......	. .	. .	4.0	. .
	1.8	2.4	7.0	0.47
		600 Calories.		

This mixture contains almost the same amount of non-nitrogenous substances as a mother's milk, but the nitrogenous substances, salts, are double the amount in mother's milk. Experience shows us, however, that children of four months or over can easily take this mixture providing that the daily quantity given does not exceed one liter from the fourth month on.

It can not be emphasized enough that we should always know the daily quantity given. This point is frequently overlooked when prescribing the mixture.

With the above mixtures one can artificially feed and raise a normal healthy infant and thousands are being thus raised today. This one point will have to be emphasized again and again, that cow's milk and sugar of milk will have to be bacterially clean if we wish to have any success in artificial feeding.

It frequently happens that the child is not satisfied with the portions given and will cry for more, as if still hungry. It is then well to add an ounce or two of oatmeal gruel so as to give the feeding more bulk. A too rapid increase in weight will also have to be watched, as it indicates overfeeding and the quantity will have to be reduced.

Another point to know is that it requires two hours to empty the stomach completely after breast-feeding and three hours after artificial feeding. The stomach should always be empty before another feeding is given. When the time approaches for a feeding the child, if healthy, will cry for its food, and it should be allowed to cry for a few minutes. The time allowance should be rigidly adhered to. Food given before the stomach has emptied itself of the preceding feeding causes distress to the child and will make it restless and give it colic.

HEUBNER'S TABLES

TABLE I

Barley meal, 100 calories to an ounce.
Oatmeal, 100 calories to an ounce.
Flour, 100 calories to an ounce.
Sugar, 100 calories to an ounce.
Whole milk, 700 calories to quart.
Skim milk, 400 calories to quart.
Buttermilk (plain), 400 calories to quart.
Buttermilk, 1.5 per cent. flour and 6 per cent. sugar, 700 calories to quart.
Skim milk, same as one-third milk. Heubner.

TABLE II

100 calories to kilo body weight.

Based on 45 calories to pound of body weight. Must feed child in 24 hours.

2 ¼ oz. to pound weight, pure milk.
2 ¼ oz. to pound weight, ⅔ mixture with barley.
2 3/5 oz. to pound weight, Heubner's ⅔ milk.
2 3/5 oz. to pound weight, Heubner's ½ mixture. (Barley.)
3 oz. to pound weight, Heubner's ⅓ mixture with barley.
3 oz. to pound weight, Heubner's ½ mixture with barley.
4 oz. to pound weight, Heubner's ⅓ mixture.

TABLE III

HEUBNER'S MIXTURE—PROTEIDS AND FATS

	Proteids.	Fats.	Sugar.	Salts.	Calories.
I. ⅓ milk	0.9	1.2	1.5	0.23	. . .
⅔ 8 per cent. sugar sol. .	. .	. .	5.8	. . .	400
	0.9	1.2	6.8	0.23	400
with barley (5 per cent)	. .	. .	3.3	. . .	500
			10.00		
	Proteids.	Fats.	Sugar.	Salts.	Calories.
II. ½ milk	1.5	1.8	2.2	0.35	. . .
½ 10 per cent. sugar sol.	. .	. .	5.0	. . .	. . .
	1.5	1.8	7.2	0.35	500
with 5 per cent, barley. .	. .	. .	2.5	. . .	600
			9.7		
III. ⅔ milk	1.8	2.4	3.0	0.47	. . .
⅓ 12 per cent. sugar . .	. .	. .	4.0	. . .	. . .
	1.8	2.4	7.0	0.47	600
with 5 per cent. barley. .	. .	. .	1.6	. . .	700
			8.6		

TABLE IV

Weight.	6th and 7th months. 700 calories. Whole milk.	4-5 months. 600 calories. ⅔ milk.	2nd 6 weeks. 500 calories. ½ milk.	1st 6 weeks. 400 calories. ⅓ milk.
lbs.	oz.	oz.	oz.	oz.
6	13½	15	18	24
7	16	17	21	28
8	18	20	24	32
9	20	23	27	36
10	22	26	30	40
11	25	29	33	. .
12	27	31	36	. .
13	29	34	. .	. .
14	31	37	. .	. .
15	34	39	. .	. .
16	36	42	. .	. .

Less than needed should be given when first starting to feed.

By adding barley one need not give over 32 ounces in 24 hours before the child is 4 months old.

The attempt of Heubner and Camerer to apply mechanical principles to the processes of nourishment of the nurslings is declared by many pediatricians to be a failure, and so viewed by many more. Having made provision for energy requirements of the child, and it does not thrive, some observers declare that the application of the law of isodynamic representation of the different foods is inadmissible; in fact, they doubt the benefit of this mode of viewing things, and with this they have declared a doctrine as worthless that in every other field or department of physiology and pathology of nutrition has given invaluable results. No physiologist who earnestly considered his subject was ever of the opinion that the mechanical conception of nutrition solved the problem; it has always been pointed out and emphasized that, in connection with and conjointly, the chemico-physiologic side of the question deserves the closest consideration.

Those who make light of so fruitful and serious a matter and are inclined to be sarcastic are referred to the article of Camerer.[1]

There is no doubt but that in considering artificial feeding from the standpoint of energy units we obtain a new vantage ground, and one point gained, and not the least, is the capability of comparing the various foods in sickness and health.

3201 Calumet Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. LACKNER AND BOWDITCH

DR. HENRY KOPLIK, New York: About fifteen years ago I had the honor to introduce the Heubner method of infant feeding into this country. I introduced it in my dispensary in New York. It was surprising to see how well a large number of children could be fed on this caloric system. I published the results of my experiences at that time in a paper on the increase in weight of infants on artificial feeding read before the American Pediatric Society. The paper received a great deal of criticism, for the percentage method was then just coming into vogue. The trouble with Heubner's system is its lack of elasticity. Heubner says that we can substitute the fats by carbohydrates, but I found that very young infants, before the third month, would not increase in weight under the exact caloric amount. I think the problem is something deeper than the caloric coefficient. It is not the normal baby that we are called on to feed. The exceptional baby we have to feed will require something else. In these exceptional babies the digestive capacity of the stomach and the gut must be considered. Some little time ago I had an opportunity to compare some of the formulas in the American text-books with the caloric method and they came very close to the caloric needs of the infants at those ages put down, and it would have been unjust to criticise these percentage formulas from a caloric standpoint. It is not simply a matter of caloric coefficient, it is not a matter of percentages alone, but it is a question of the individual baby pure and simple.

---

[1] Jahrb. d. Kinderh., lvi.

Dr. L. T. Royster, Norfolk, Va.: We can not go by rule of thumb in feeding infants; the baby is to be studied. When I was a student in New York the feeding was done by a whole algebraic coefficient at which time the protein was vilified for all the troubles in infants. A little later the top feeding came along to simplify things, and it was very fortunate indeed. Then the fat was blamed almost entirely. In every instance in which a problem has been apparently solved, shortly thereafter the pendulum has swung away from that to the farthest extent. One of the older philosophers has said that "experience is fallacious," but through experience only can we acquire judgment, and only through seeing a large number of patients can any one determine that a certain formula will meet the requirements. And judgment, in the final analysis, is the court of appeal in the individual case.

Dr. J. P. Crozer Griffith, Philadelphia: I wish to compare the so-called American method of feeding with the German or "caloric" method. The trouble with the German method, as applied to infant feeding, seems to me to be its lack of elasticity. For instance, Biedert, years ago, developed in a thoroughly scientific manner certain "cream-mixtures," Nos. 1, 2, and so on. They were scientifically correct and it was a baby's duty to thrive on them. If the child did not thrive it was it's fault, not that of the mixtures. Then came the Backhaus mixtures, made fixed in the same way, and next put on the market as proprietary preparations. In fact, it is noteworthy that, contrary to the custom in America, many of the German proprietary foods were devised and named by physicians before they were patented. I do not question that German medicine, taking it all in all, is much ahead of us in the scientific study of infants and of the food which they require, based on the amount of nitrogen, phosphorus, and the like, ingested and excreted; but I think the American physician gives more attention to the needs of the child as an individual; his method is more elastic. The trouble with the caloric method, I think, is that, although scientifically exact, it can not be applied as well practically. It does not take into sufficient account the character of the food and the susceptibility of the individual child to certain ingredients. I consider it an excellent check on other methods of feeding, because by it we can tell whether a child is receiving a diet strong enough in calories to permit it to thrive.

Dr. Frank S. Churchill, Chicago: I am a believer in the percentage method of feeding because I consider it the best, and we ought to take the best wherever we find it. I was taught twenty years ago that the individual baby must be considered in this matter of feeding, and have seen no reason to change my opinion since. Every individual must have a certain amount of food; he must also have a certain amount of fat, carbohydrate, proteid, etc., to meet the requirements of the system. We must figure out, so far as possible, just how much fat, sugar and proteid each individual, each baby, needs. At present we must depend more or less on our judgment as to what are these requirements; in the future I think that the physiologic chemists will give us much help in this direction. After determining what the baby needs, the caloric method may act as a check in helping us determine just how much the baby needs. In feeding atrophic babies especially I have found it of value to "check up" by calories, to prevent over-feeding. Yet the caloric method alone is not sufficient. For instance, I have seen babies fed by the caloric method alone, no attention being paid to the percentages of the different ingredients in the diet. The total calories were all right, according to the baby's weight, but he was not gaining in weight. Analysis of the formula would show that the fat was low (the advocates of the caloric method are fearful of fat), and correction in this direction resulted in the desired gain. We must have a well-balanced formula in feeding babies.

Dr. H. D. Chapin, New York: One thing has not been taken into consideration in the comparison of the two systems. The feeding of the baby is practically for tissue growth. According to the caloric system we can run up the carbohydrates and leave out the fats and get the calories just right. We have just got our students educated up to the percentage system for food values, and if we are going to give them a long system of calories they will throw up their hands. There is no comparison between the two systems because the percentage system is right and the caloric system is only half right. The caloric system puts the emphasis in the wrong place.

Dr. C. G. Kerley, New York: Recently I investigated about 100 histories of infants ranging from 1 to 12 months of age who had thriven satisfactorily on artificial feeding. I estimated the caloric value of the daily amount of food each child had received. The infants were well, thriving and happy. I found that they had been getting from 100 to 300 calories a day more than Heubner's method called for. Since then I have attempted to feed other children according to the supposed caloric method and found that the New York baby is not satisfied and does not thrive when fed in this way. In fact, it was absolutely imperative to give more nourishment, as the children were hungry and failed to grow. If I had not given these babies food of a higher caloric value than Heubner states is necessary they soon would have ceased to be my patients. The element of waste is very important in the nutrition of children. Not all by any means is utilized that passes into the stomach. In one case, a physician's child, 3 months of age, I had to give 300 calories more daily than Heubner states is necessary. He had to have it. His father said he could not live in the house with him otherwise.

Dr. Charles Douglas, Detroit: Dr. Kerley's are exactly the principles I have been compelled to follow. A child of one month will digest more fat and more protein in proportion than a child of six months. I frequently find a child working up on a certain food, increasing steadily and without a single change in the food. If the caloric system were applied to that child with an increase in weight more calories would have to be given. I find that a child needs to be comfortable and happy, a happy child is always a successful child. A child who does not sleep and is not happy is not getting the right kind of food, or he is not getting enough or else too much food. Children vary in their digestive power at different ages. They digest the most simple parts of the carbohydrates and fats given them and the rest they throw away. The food that makes them comfortable is the best we can give them, and we must meet the child's ability in this regard.

Dr. Walter D. Ludlum, Brooklyn: I have been more and more impressed with the worthlessness of the caloric method. I, too, have compared the average percentage formulas with the caloric and I have worked out the calories, and I find that in every case more is actually needed for the child's nutrition than is required by the Heubner method. I have used the Heubner method only as a check, for it provides for the sum total of the caloric value of the food and not for the different elements of it. If it is to be popularized it must be simplified beyond the present arrangement. To place such a chart as that before a class of students, or even of physicians, simply horrifies them.

Dr. D. J. M. Miller, Atlantic City: For many years I have been connected with the Children's Hospital of Philadelphia, and I have been impressed with the fact that the young physicians serving as internes have not been taught the principles of artificial feeding of infants. I hope that this discussion will be productive of one thing at least, *i. e.*, that students will be taught the basic principles of infant feeding and not the method of this and that man, for they are taught methods and not principles, now, and those of us who are interested in children see the disastrous results of this plan of teaching. One of the most successful feeders of babies that this country has ever had, the late Dr. John F. Meigs of Philadelphia, said that the most successful physician for a baby was the man who adapted himself to the needs of the particular baby.

Dr. John Lovett Morse, Boston: The gentlemen who have preceded me have voiced well my feelings as to Heubner's system of feeding. I have found the calculation of the caloric value of food useful as a check to prevent both over-feeding and under-feeding. It seems to me that there is a very general misapprehension in the middle west as to what is meant by the percentage method of infant feeding. The percentage method is not a method of feeding; it is simply a means of knowing accurately what we are giving the baby. We try to feed adults accurately and we write our prescriptions accurately. Why should we not determine accurately what we are feeding babies? There are many men in this country who, it seems to me, are ready to accept anything which comes from Germany without investigation or consideration and without comparison with American methods. Pediatricians in this country know what is being done in Germany; those in Germany know little or nothing of what is being done here. Judging from their writings, they are almost entirely ignorant of the best American methods of infant feeding. I believe that what German pediatricians most need at present is a course in infant feeding in some of our eastern cities.

Dr. H. T. Price, Pittsburg, Pa: From the discussion here it would seem that all the German babies artificially fed should die. The foundation of the Heubner system is simply the aim to feed a low fat. Every sensible man will feed a baby what it should be fed to make it grow. The foundation of the Heubner school is chiefly a lower fat than has been the custom.

Dr. Ernest Lackner, Chicago: I would like to know what Dr. Morse would do without tuberculin or any of the other things we use every day and for which we are indebted to the Germans. The Germans have the necessary schools and establishments for the pursuit of scientific work. Scientific matters are neither American nor European, they are universal, and any man who will criticise any physician for doing things as *Germany is doing to-day should reconsider his remarks. What* von Behring is doing to-day is enough, for through his efforts hundreds of thousands of lives are being saved. What is Ehrlich doing? The work of these men is certainly not American. This idea of being patriotic in science is impossible. I have given you to understand what Heubner means by his method of feeding. Heubner's *feeding* is *not caloric, he has simply re*duced down to calories and to energy units the food given the baby. I have a letter here from Heubner on this subject that will answer most of these objections in a general way. Cow's milk is not fitted for the infant, it has to be modified. Each child will have to be examined closely as to its idiosyncrasies in taking fat. Start with a low percentage of fat and work up. The Germans are not advocates of a low percentage of fat, they are simply trying to fit the amount of fat to the capacity of the child. As to the sugar, there are three which may be used. Jacobi has recommended cane sugar, and one disadvantage is that when you want to wean the child it does not like to be weaned from this very sweet mixture to something else. Then there is lactose or sugar of milk. It is slow in adding to the weight, but you can give large quantities of it and a child will seemingly scarcely gain in weight at all. By the addition of maltose it will increase very rapidly. Lactose must go through a certain process in the digestive canal, but maltose passes directly through the intestinal canal, and is worked on in the system. The child can be given twice as much maltose as cane sugar or lactose. Finkelstein explains how to determine the amount by Heubner's system.

Dr. H. J. Bowditch, Boston: I am glad Dr. Morse said what he did about the percentage system of feeding. It is true that food for one is poison for another, and this is just as true in the feeding of babies as in adults. This trigonometry table may be of value but it is not a thing that should be taught to a student. The question has come up as to what should be taught the student. When I went abroad I found they were teaching the caloric method. I did not know anything about it and so was much handicapped. Students should be taught what it means and how, in the simplest form, calories are calculated, but we further ought to teach the student that it is not a method of feeding children. Every child has to be fed according to what we have discovered from its symptoms, its movements, and changes in the food.

THE INFLUENCE OF THE OLFACTORIES ON DIGESTION

GEORGE M. NILES, M.D.
ATLANTA, GA.

The sense of smell is probably the least valued of the five senses, and the rôle it plays in many of the important bodily functions is least appreciated by the human race. Among the lower animals it is more essential, for by this sense they find and select their food, as well as detect the approach of danger. Some of the savage, or so-called wild people, have this faculty as highly developed as the lower animals, and Humboldt tells us of some Peruvian Indians who could follow the scent of game as well as hunting dogs.

These facts, though interesting, do not come within the scope of this article, and, in order properly to discuss the influence of the olfactories on digestion, we should study this subject from an anatomic, a physiologic, and a psychic standpoint. It may be well to remind the reader briefly that the area of the terminal expansion of the olfactory nerve, the olfactory region, covers an area only about the size of a ten-cent piece in man, including only the upper part of the septum and the islands of the superior turbinate; detached islands are found in the vicinity of this chief olfactory region, but the remainder of the nasal cavity is fitted and used for respiratory purposes only.

There are certain essential differences between the olfactory and respiratory regions, the principal ones being as follows: The olfactory region possesses thicker mucous membrane, but is covered with only one layer of cylindrical epithelium, and contains a yellow or brownish-red pigment, while the respiratory region has a double layer of ciliated epithelium mixed with some goblet cells. The main difference, however, lies in the presence of the end organs of the olfactory nerves and the olfactory cells which lie scattered between the long cylindrical epithelial cells of the surface; also the fine olfactory hairs are present, projecting through the pores of a delicate structureless limiting membrane, covering the surface of the epithelium. It will be noted that the area devoted to smell is situated as far as possible from the external nares.

The sensation of smell is elicited by the presence of odorous substances in a gaseous state, coming in direct contact with the olfactory cells or hairs. This generally occurs during inspiration; but odors received through the mouth, and then expelled through the nostrils, may be smelled, though not accurately.

The first moment of contact of the odorous substance with the olfactories seems to be the most effective, for they soon "tire" of a continuous odor, and may be absolutely insensible to it, while retaining their usual acuteness for a different one; for this reason it is best to sniff, or take frequent short inhalations with the mouth closed. Some vaporous substances, especially those with pungent qualities, seem to act simultaneously on both the olfactory and gustatory senses, and Zwaardemaker describes some structures found in the olfactory region similar to taste buds. Nagel thinks, however, that this is only a stimulation of the gustatory nerves on the posterior side of the uvula.

While a morsel of food is being masticated there is free communication with the nasopharynx, except during the instant of swallowing. Immediately afterward a moist vapor charged with the odor of the substance in the mouth is carried into the nose. It is at this moment, but not while the fluid remains in the mouth, that one "tastes" the aroma or bouquet of drinks. This faculty of combining smell and taste in a discriminating manner is highly cultivated by those who make a profession of judging the various teas and wines.

The digestion may be influenced by the olfactories in several ways—directly, reflexly through idiosyncrasy, or by some complex psychic process hard to analyze. It is estimated that it requires about 2,000 cubic feet of air to pass daily through the lungs of an adult in order to furnish enough oxygen to maintain good digestion, and, as the greater part of this air passes over the olfactory region, the content of odorous substances it contains may exert a marked effect on the alimentary tract.

That appetizing odors may make the mouth "water" by stimulating the salivary glands is well known, and Pawlow has shown that the gastric juices are fully as susceptible to the gentle suggestions of the olfactory organs. Every one who reads these lines can doubtless remember a past experience, when fragrant odors wafted by friendly breezes from some near-by kitchen not only whetted the appetite, but also brought about in the stomach that gnawing sensation which only a bountiful flow of the digestive juices can produce.

On the other hand, no one factor can exercise a more malign influence over the appetite, and with it the digestion, than foul or repulsive smells; for we must admit that, as Bassler well says, "viewing the body as a whole, a marked disturbance in any organ outside of the digestive canal acts as a chestnut-burr irritation in upsetting the normal nervous balance of the neurologic system, and that these abnormal stimuli manifest their effects most easily on the digestive organs, which, through abundant sympathetic supply, are most sensitively balanced." As some loathsome sight or a disgusting mental picture may kill the appetite and "turn" the stomach, so a foul odor, through its reflex action, may just as effectually dry up the "appetite juices." Even after digestion has normally begun, the presence of a disagreeable odor may retard its progress, and, by inhibiting the secretion of gastric juice, and checking the motor waves of the stomach, may allow stagnation, bacterial fermentation, and the formation of gasses and irritant decomposition products.

The influence of odors and perfumes on many people is exceedingly marked. Some there are who can not remain where lilacs are in full bloom, or bear the odor of jasmin; others are given a headache or are nauseated by heliotrope or tuberose, while the smell of cantharides often causes vertigo and a sinking sensation in the epigastrium. Even the fragrance of roses has an irritating and nauseating effect on some. Attacks of real illness, with long trains of digestive disorders following in their wake, may be brought on by odors.

I recently saw, with Dr. J. L. Campbell of Atlanta, a middle-aged woman who was affected with nausea and vomiting by the smell of fish, mutton, turpentine or butter-beans, and, unless she got away from these odors quickly, severe purging and prostration set in, rendering her as ill as if she had been suffering from some form of ptomain-poisoning. Strange to say, she could eat either fish or mutton with relish, and without any discomfort, if she could prevent their odors from reaching her olfactories.

I have seen several individuals who, having been made sick by some article of diet in the past, experienced the most lively repugnance and nausea at the slightest whiff of the well-remembered article for months or years afterward.

Dr. J. D. Thomson of this city has reported to me the case of a veteran of the late war between the states, who was surfeited with onions during his war-time experience. The cooking facilities in camp being limited, the taste and odor of onions permeated every mouthful of food and drink, and now, after a lapse of over forty years, he can not eat in comfort where the smell of this vegetable is in evidence.

That offensive odors may not only derange the digestion, but may cause even death, and that the most horrible, was recognized about the time of Alexander the Great. One of the methods then used for executing a criminal guilty of some specially revolting crime was to manacle the living man hand to hand, foot to foot, and neck to neck to a dead body; and it was found that the vile effluvia emanating from every pore of the putrefying corpse, coupled with the awful psychic abhorrence, speedily quenched the vital spark of the hapless victim, no matter how powerful the physique or callous the mind.

Every intelligent observer will grant that these resentments to odors, in some cases, are real idiosyncrasies and not the manifestation of pretense or prejudice. The fact can be explained only as a pathologic phenomenon exerting its main force on the most vulnerable point of the human economy, the gastrointestinal tract. Such conditions can occasionally be aided by a general toning up of an unstable nervous system, but, as a usual rule, the only safety lies in avoidance, if possible, of the repulsive odors.

As offending scents may set in motion a train of morbid digestive symptoms, so, on the contrary, those that are sweet and agreeable may exercise a highly beneficial effect. The Orientals appreciate much more than we the delightfully soothing influence of pleasing perfumes, having developed within themselves to a notable degree the faculty of deriving the most enjoyment from inhaling fragrant odors. The most beautiful creations pictured in the imagination of Mohammedans are the houris, represented in the Koran as nymphs of Paradise, formed of musk, who exhale from their lovely bodies entrancing perfumes.

We are told by travelers that it is the custom of many Eastern peoples to spend after each meal a season of quiet, while the air around them is rendered fragrant by a fine mist; or, this not being convenient, a bottle of their favorite perfume is constantly inhaled. Even the poorest indulge in this habit, for they all, rich and poor alike, feel that it benefits both their nerves and digestion. By smokers the aroma of tobacco is greatly prized, and all unprejudiced observers will grant that a good cigar, coupled with a serene mind, will often materially help in the proper disposal of a hearty meal. Many have also noticed the speedy peristalsis of the bowels, which would otherwise be lacking, set up by an after-breakfast smoke.

It would seem that a psychic state favorable to the digestive processes may be induced through the olfactories fully as well as through the other senses, and I believe that this almost fallow field may be cultivated profitably by the gastroenterologists.

Since we admit that the commonly seen symptoms of cessation of digestion, spasms of the cardia or pylorus, anorexia, nausea, vomiting or diarrhea may be brought on by insulted olfactory organs; and, as all of us realize the danger to individuals and communities from noxious vapors, it would seem a worthy endeavor to study these agencies intelligently, that we may avoid the evil and extract the good that in them lies.

The different functions of the body vary in their importance as do different stars in brilliancy, but each has its proper rôle, exerting its own quota of authority. Let us not, therefore, deem unimportant this humble faculty of smell, which, though modest, is always alert and discriminating, and whose influence over the whole digestive system is becoming more and more appreciated.

409 Candler Building.

A STUDY OF THE ANATOMY AND THE CLINICAL IMPORTANCE OF THE SACRO-ILIAC JOINT*

FRED H. ALBEE, M.D.
Instructor in Orthopedic Surgery, College of Physicians and Surgeons and Post-Graduate Medical School and Hospital; Visiting Surgeon, Home for Crippled Children, Hawthorne.
NEW YORK

Some time ago the writer was much surprised, on reading the literature of the minute anatomy of the sacro-iliac joint or synchondrosis, to find such a marked disagreement among the most prominent anatomists and gynecologists. To quote in brief from some of them: Morris holds that even the presence of synovial membrane is not constant, stating that it is more apt to be present in the female. Luschka believes that a small amount of synovial membrane is always present and that it increases in size at times of pregnancy. Cunningham states that the synovial cavity is imperfect and rudimentary, but believes that hyaline articular cartilage exists usually. Testut, the great French anatomist, mentions certain folds of synovial membrane which occur here and there, filling up gaps or margins of the fibrocartilage. Morris denies that there is any appreciable movement at this synchondrosis. Williams (in 1903) states that "the articulation between ilium and sacrum is described as a synchondrosis, but is really a joint, on account of the presence always of more or less synovial membrane." Kuttner asserts that it is a joint with motion and that the horizontal position increases the true conjugate diameter of the pelvis by 6 mm. and Walcher's position by 9 mm., as compared with the lithotomy position.

On account of the above-mentioned disagreement of the best authorities as to the anatomy of this joint, with emphasis on the term "joint" rather than synchondrosis, I was induced to ascertain, if possible, by the dissection of a sufficient number of joints, its true anatomy. By the kindness of Professor Haynes an abundance of material was furnished me at the Cornell University Medical College.

The results of this work are briefly as follows: In the careful dissection of fifty specimens a perfect joint, composed of all its elements, such as synovial membrane and cavity, and strong well-formed capsule was found in each instance, and proved to be as constant in its size and relations as any other joint. Before opening the joints many were injected with an aqueous solution of methylene blue, which colored the synovial membrane so that it could be seen to distend and retract all along the anterior-inferior aspect of the joint when motion was elicited. This part of the capsule is very thin, which accounts for the fact that infection of this joint is very prone to discharge by this avenue into the pelvis and rarely through the very thick part of the capsule posteriorly; also, this part of the capsule often ruptures in symphysiotomy, and in case of puerperal sepsis opens the joint to infection. Sansten states that it ruptures in 44 per cent. of cadavers below 6 c.c. of pubic separation. The lumbosacral cord passes in close proximity to the joint at its lower third, and undoubtedly is frequently involved in affections of this joint, thus explaining the presence of persistent pain in the distribution of this nerve, i. e., sciatica.

The articulation is easily opened by incising the anterior part of the capsule and forcing the pelvic bones apart in front, the symphysis pubis having already been separated. The sacrum and the ilium swing on the posterior and interosseous ligaments, as a door on its hinges. Hence the infrequent interference with locomotion and permanent injury of this joint following symphysiotomy.

In my dissections the interosseous ligament always separated from the ilium and never from the sacrum. The round ligament sometimes ruptured and sometimes its bony attachment. The anterior or auricular portion of each articular surface was covered with a thin plate of cartilage, which was thicker on the sacrum than on the ilium. It averaged, in the fifty specimens, in its greatest length, 7 cm. (2 3/5 inches), and in width 3 cm. (1⅛ inches). The largest joint area of hyaline cartilage was 8 cm. (3 1/16 inches) in length and 3 cm. (1⅛ inches) in width. The smallest was 6 cm. (2¼ inches) in length and averaged in width 2½ cm. (15/16 inches).

The posterior irregular part is the attachment of the interosseous and round ligaments, around the latter of which most of the motion occurs as about an axis. One joint was affected with osteoarthritis and the anterior part of the joint was obliterated with bony deposit, which also extended into the posterior ligament.

Let us now consider briefly the mechanics of this articulation. The sacrum is an inverted key to an arch suspended principally by the posterior sacroiliac ligament. The base of the sacrum, in the upright position, projects forward beyond the articular surfaces of the ilium and has a tendency to tip down. This is prevented by the sacrosciatic ligaments, which tie the lower part of the sacrum to the ischium. Here is a great articulation placed at the cross-roads, so to speak, between the trunk and the thighs and mechanically imperfectly constructed to sustain sprains and injuries.

Distinct motion was elicited and measured carefully in every specimen except one and motion was absent here, as stated above. These researches were carried on in conjunction with Dr. Henry L. Taylor and will be reserved for a future publication. Sixteen of the cadavers were placed in Walcher's position[1] and the true conjugate diameter of the pelvis averaged an increase of 8 mm. (⅓ inch). Walcher obtained 9 mm. on the living subject.

My interest in the pathology of this joint was first stimulated by seeing a case of relaxation of this joint with Dr. Goldthwait of Boston in 1903. This was before the publication of the monograph on this subject by Dr. Goldthwait and Dr. Osgood, who were the first to demonstrate the existence of such a condition. The relaxation in the case referred to was caused by lying for a very long time in the position of dorsal decubitus following a pelvic operation.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

* From the anatomic laboratory of Cornell University Medical College

[1] Patient on back with her legs hanging over the edge of the table.

Under favorable circumstances, however, this joint will stand much abuse, as in the case of a symphysiotomy. Edgar reported five cases in which he obtained from 2 to 2½ inches of separation at the symphysis followed by firm union and without symptoms. Nevertheless, this articulation is liable to all the affections of other joints and in the event of infection the prognosis is often serious, because, first, it is very likely to be a metastatic infection from some other part of the body, and, second, as described above, on account of the danger of spontaneous drainage forward into the pelvis.

ILLUSTRATIVE CASES

Case 1.—*History.*—Miss N. M., was seen by me Feb. 25, 1906. She worked in a web factory; her previous history was negative. Last October she fell over a large stone in the country and strained her back, and was in bed two weeks. This was followed by inability to stoop, lie on back, or stand on right foot, without severe pain in extreme lower part of the back, which always remained in the same place and became more severe at her menstrual periods. The patient's only comfortable posture was lying on the left side.

Physical Examination.—Total lateral spinal curvature to the left. Spine normally flexible. Hip and other joints normal. Very distinct tenderness over lower part of right sacroiliac joint. Goldthwait's symptom present, i. e., pain in region of sacroiliac articulation, when the thigh was flexed with extended leg to a right angle or less. Pain produced by standing on right foot; most severe, however, when patient attempted to turn over, while in a reclining position.

Treatment.—Pelvis was encircled by very tight two-inch bands of surgeons' adhesive plaster just below the anterior-superior spines of the ilia. Patient reported in one week entire relief. The strapping was reapplied, at periods of a week, four times. A long corset with a four-inch elastic webbing belt at bottom to grasp the pelvis was then made, which has been worn with entire relief every since.

Case 2.—*History.*—Miss A. O., aged 15, was referred to me by Dr. A. A. Crane, Waterbury, Conn., Feb. 20, 1906. She attended school and practiced on the piano a good deal. Previous history was negative. The patient has had pain continuously in lower part of back ever since falling on the ice three years before. There was an increase of pain at the time of each menstrual period, although menstrual fluid had not appeared. Pain was produced by walking, sitting, especially on the affected side, or laying on the back. The patient never lays on the back, always on the left side.

Physical Examination.—Fairly well developed and nourished girl. Examination negative except for marked total spinal curvature to the left. No rotation. Tenderness over upper part of right sacroiliac joint. Spine normally flexible except in its extreme lower part. Goldthwait's symptom markedly present. Pain elicited by patient standing on right foot and lying on the back.

Treatment.—This was same as first case. The relief was marked, although for three years the patient had been under constant treatment without the slightest amelioration of the symptoms. Three months later the patient reported that relief had continued and that she had gained ten pounds in weight.

I am indebted to Dr. H. H. A. Beach and Dr. R. B. Osgood for the privilege of reporting the following case:

Case 3.—*History.*—F. C. R., a man, aged 23, entered the Massachusetts General Hospital, Dr. Beach's service, Sept. 28, 1905; occupation, mechanic. Past history was negative; no rheumatism. Three months before, while carrying one end of a heavy canoe the patient stepped into a hole and felt something slip in the lower part of his back. This was followed immediately by pain when sitting or turning in bed. The patient and his friends noticed that his right hip was becoming more prominent than the left. The pain increased also.

Physical Examination.—Very frail physique. Thorax and abdomen negative. Body tilted to left when patient stood, set or reclined. Flexing extended leg on pelvis caused pain when a right angle was reached. Forward and backward motions showed that the spine is held rigidly on the pelvis. Lateral motions of the spine were normal, from the mid-dorsal region upward. An *x*-ray picture showed a dislocation of the right sacroiliac joint.

Treatment.—Ether was given October 6 and Dr. Osgood reduced "the right ilium to its normal position, so that its crest came on the same level as that of the left ilium and so that the sacrum seemed in its normal relations." A long plaster-of-Paris jacket extending well over the hips was then applied, with the lumbar spine in extreme lordosis. I saw this patient Oct. 8, 1905, and at that time he was walking about without pain or deformity.

Case 4.—*Patient.*—M. G., a married woman, aged 35, was seen at the Post Graduate Hospital in June, 1906. Past history was negative. One year ago patient had a very difficult labor, forceps having been necessary. The convalescence was normal except for a great deal of trouble with the lower part of the back, on account of which she remained in bed six months. Patient stated that the first thing she noticed was pain and "a grating sensation" in that region, and indicated the left sacroiliac joint as its location. The grating lasted two months and slowly disappeared. The pain, however, persisted unabated and was much exaggerated at her menstrual periods. Stooping, standing on left foot and lying on back, caused pain in this region.

Physical Examination.—Patient well nourished. Total spinal curvature to right, patient sitting more comfortably on the right side. Tenderness to deep pressure over lower part of the left sacroiliac joint. Goldthwait's symptom present.

Treatment.—Pelvis was strapped and relief was immediate. The strapping was continued for six weeks and then a long corset with a webbing belt was fitted. The relief had continued when the patient was last seen.

Case 5.—Dr. M. H. was attending the lectures at the Post-Graduate Medical School in July, 1907, when I demonstrated a case similar to the above cases. The relief from the strapping was so marked that the patient threatened to leave a cane, on which he was so dependent only a few minutes before. Dr. M. H. was so impressed with the similarity of his own symptoms that, after the lecture, he came to me and stated that he felt sure that he was suffering from the same condition. He said that he had sought relief without avail, from many sources, including his colleagues and several members of the faculties of the Post Graduate Medical School and the Rush Medical School in Chicago, of which latter school he was a graduate. He had been thrown from the back of a horse two and a half years before, from which time symptoms dated. The result from the above-mentioned treatment in his case was as striking as in the case he had just seen.

A sixth case represents, with the postoperative case already cited, a class in which a relaxation occurs from a long-continued strain on the ligaments, as contrasted with a sudden trauma.

Case 6.—The patient was a man aged 45; his symptoms dated from the time he had held, for a considerable time, in a stooping position, a heavy plate-glass window, while a fellow workman fastened it in place. This patient had a convalescence similar to the others but slightly prolonged, which, by the way, is very liable to be the case in this type of trauma, according to my experience.

Case 7.—*History.*—M. G., a man, aged 21, was seen May 12, 1907. For the past year the right knee had been very painful and had been in a plaster-of-Paris splint most of the time. The patient had used crutches most of the time. His general health had declined and he had lost considerable weight. Four months before he was seen he began to have pain in the lower part of the back, especially when walking, stooping or turning over in bed. The past few weeks the pain had become much more severe. The decline in the general condition had been more rapid. The appetite had become very poor and the patient thought that he had a fever each afternoon.

Physical Examination.—The patient was very poorly nourished and pale; temperature 101 F. at 3 p. m. There was considerable swelling about the right knee. It was flexed about 15 degrees and very sensitive to slight passive motion. Condyles of femur were apparently enlarged; tibia somewhat subluxated.

There was a total lateral curvature of the spine to the left. The lumbar region was held very rigidly. There was considerable swelling and deep fluctuation over the right side of the sacrum. A rectal examination disclosed a tumefaction and questionable fluctuation on the right side of the pelvis in the region of the anterior-inferior part of the sacroiliac joint. A diagnosis of tuberculosis of the knee and the right sacroiliac joint, with secondary infection and rupture of the latter into the pelvis was made.

Treatment.—An incision over and down to the joint was made posteriorly. The portion of the ilium overhanging and obscuring the joint was chiseled away and apparently good drainage secured. The patient rallied somewhat after the operation and disappeared from observation. His death was reported two months later.

CONCLUSIONS

1. The sacroiliac articulation has all the elements of a joint and therefore has a similar pathology.
2. It has motion and plays an important rôle in labor.
3. Its variation, according to individual, age or sex, is very slight.
4. Its anatomy is such that drainage into the pelvis is very apt to occur, and, therefore, in the event of infection, early posterior drainage is often indicated.
5. Its affections are, undoubtedly, the cause of many obscure and unexplained backaches and persistent sciaticas.
6. The important ligaments of this joint are so placed that the sacrum and the ilium swing open, in the event of a symphysiotomy, as described above, and little permanent damage results, even if the pubic separation has been great enough to rupture the unimportant anterior-inferior part of the capsule.
7. The relaxation of this articulation should be guarded against by support of the lumbar spine with pillows, etc., in cases of protracted postoperative convalescence. Undoubtedly, many here can recall instances of Nature's warning, in the form of a convalescent's backache, which the nurse so readily relieved by merely placing a pillow under the lumbar spine.

125 West Fifty-eighth Street.

ABSTRACT OF DISCUSSION

DR. C. C. FREDERICK, Buffalo: The important point that the paper raises is the differential diagnosis between conditions in the female pelvis that are due to pathology of the female pelvic organs and those conditions which so simulate disease of the pelvic organs, but are not due to disease of these organs but to the conditions that Dr. Albee has just mentioned. Over a long series of years we have all had women come to us, young and old who have been treated by all the various methods employed for the relief of pain in the back, pain down over the appendix, pain in the ovarian region, tenderness in the pelvis, etc., the pelvic organs being blamed for the pain, discomfort and neurasthenia. If we go back into the history of these women we will find a fall or accident to which at the time little attention was paid. Gradually, however, symptoms developed over a number of years and the women have become semi-invalids with neurasthenic symptoms, pain in the pelvis, dysmenorrhea and all the ills of women. A pelvic examination in every one of these cases will elicit the greatest amount of hyperesthesia. The vagina, uterus, tubes, introitus are tender. Every bit of tissue below the brim is tender, presumably due to some intrapelvic condition. The patients have been tamponed and treated and it is almost impossible to convince the attending physician and the patient that the condition is not intrapelvic but due to trouble in the sacroiliac joint. This can be easily proved in a certain number of cases by the relief that comes from good hip support and support of the iliac joint. The period of time that elapses and the persistence with which the treatment must be followed up, the slowness of recovery from the injuries done to the tissues about the sacroiliac joint, and especially to the delicate nerve distribution make the hope of the patient ofttimes drop below par and cause her to think that a mistake in diagnosis has been made. I believe, however, that almost every one of these patients can be cured by the use of the hip bandage, leaving out of the treatment all intrapelvic tinkering and everything addressed to the intrapelvic organs. I have seen women whose ovaries have been removed, who have been curetted and subjected to other operative procedures and yet the pain has persisted.

DR. REUBEN PETERSON, Ann Arbor: I want to speak of just one phase of the subject, not of the difficulty of diagnosis in these cases—although we know that that is hard enough. If one is not fortunate enough to be associated with a competent orthopedic surgeon I have found it most difficult to make a correct diagnosis, for it is by no means a simple matter to say in one case, this is due to pelvic disease, and in another this is the result of sacroiliac disease. Some time ago I looked into the question of the pain my patients experienced after operation. It seemed to me that it was all out of proportion to what it should be, and almost invariably the pain was in the back. I have no doubt that others have had the same experience with patients after operations. Finally, my head nurse suggested that the pain might be due to the patients lying for some time on a hard operating table. At that time we used the ordinary pad seen on most operating tables. This pad was changed to one made like a mattress, between two and three inches thick, and covered with rubber with a sterilized covering over that. Ever since I have employed this kind of pad for my operative work, even in prolonged operations, my patients have not suffered pain in the back. Then I had the pleasure of hearing it scientifically explained by Dr. Goldthwait of Boston, who showed that either in the Trendelenburg or the lithotomy position, when the assistant inadvertently leans on the legs of the patient, strain comes on the sacroiliac joint. Many times we have relieved the pelvic condition but our patients have been worse because of this sacroiliac strain. We are just beginning the study of this complication and it is only by working in conjunction with an orthopedist or studying under him, that the gynecologist can ever make headway in the treatment of pain in the sacroiliac region. Certainly it has opened up a field that the gynecologist never before suspected and the results of such study ought to be of great assistance to our patients.

DR. C. W. BARRETT, Chicago: I recall a case in which with pelvic infection following abortion there was inflammation of the sacroiliac joint, giving marked tenderness on deep pressure over that joint, but more marked tenderness on succussion of the pelvis. Succussion on the trochanters and crests of the ilium gave marked pain in the right sacroiliac joint. The treatment of the pelvic infection caused that to subside, or it subsided, without treatment and the joint recovered from the inflammation without any drainage or any direct treatment for that condition.

DR. MYER SOLIS COHEN, Philadelphia: I think this discussion should not close without mention of Dr. Goldthwait's work regarding the conditions caused by straining of the sacroiliac joints. He shows that by standing in an improper position the curve of the spine is lost, the sacrum tilted backward, and strain put on the sacroiliac ligament. He also shows that the straight front corset and other bad forms of clothing cause lordosis which tilts the sacrum forward, thus also straining the sacroiliac ligaments. He also calls attention to accidents such as falling from horseback as being responsible for this condition.

DR. A. J. WINEBRAKE, Scranton, Pa.: The sacroiliac joint is more abused from ignorance than any other joint in the body. It is much abused by the ignorant practitioner in the application of forceps who has no time to wait and knows nothing of the mechanism of labor. He makes the high application of forceps and pulls with all his brute strength and the patient is rendered practically an invalid, due to injury to this joint and soft parts. This abuse is going on all over the country. In the race for money men have not time to wait in the practice of obstetrics and give Nature a chance. We are taught not to make examinations because there is always danger of infection. This is a grave mistake. An examination can be made with safety if the examiner is as careful in putting the finger into the vagina as in putting it into the abdomen. Something will then be known about the mechanism of labor in the abnormal case. It is surprising how many turns the head will make which cannot be guilded with a pair of forceps. I think that Cesarean section is a simpler operation than high forceps application. The latter operation in my opinion requires more mechanical skill and more good judgment than Cesarean section.

KELOID: A COMPARATIVE HISTOLOGIC STUDY *

M. L. HEIDINGSFELD, Ph.B., M.D.
Professor of Dermatology, Medical Department, University of Cincinnati; Dermatologist to the Cincinnati Hospital
CINCINNATI

Reduplication of fibroconnective tissue of the skin to the extent of inducing tumor formation of neoplastic character is probably one of the most infrequent of histologic anomalies. This is all the more remarkable when we realize its abundant and universal distribution, the facility and promptness with which it reproduces itself and its constant exposure to insult and injury. Fibroconnective tissue stands in marked contrast, in these respects, to the other elements and structures of the skin, namely, the epidermis, hair follicles, sweat and sebaceous glands. The latter show a more marked tendency to reduplicate themselves to the degree of tumor formation and pathologic overgrowth, and when they are traumatically or pathologically removed or destroyed, with the exception of the epidermis, are prone to be replaced by fibroconnective tissue.

The clearest and probably the purest and most common type of fibroconnective tissue tumor or new growth is keloid. Many pathologic affections of the skin, namely, molluscum fibrosum, multiple fibroid new growths (so called), myofibromata, neurofibromata, angiofibromata, etc., have been erroneously classed with the fibromata and do not possess a clinical or a histopathologic analogy. We occasionally meet circumscribed lesions of pure fibroconnective tissue of varying size, with elevation, consistence, dimensions and definite proportions, either imbedded in the cutis and subjacent tissues, or lying freely on the surface, which are the direct result of the prolonged reaction of the tissues against the presence of a foreign body, or some other form of protracted irritation. These lesions are histologically pure fibromata, but are essentially non-pathologic and non-neoplastic in character, inasmuch as they possess no innate tendencies to enlarge or encroach on healthy areas, but expend their energies against diseased or pathologic agencies of which they are the indirect result. They are not, properly speaking, tumors or new growths in the commonly accepted sense of these terms. The same is true of the hypertrophic cicatrices which are the result of syphilitic, tuberculous and similar processes which primarily or secondarily involve the skin. Inasmuch as they are the indirect result of conservative agencies against pathologic and diseased conditions, they are not fibromata in a pathologic sense, though they possess an identical or indistinguishable histologic structure.

The disposition to divide keloid into true and false, and again to differentiate the latter carefully from hypertrophic and ordinary scar tissue on clinical and histologic grounds, although becoming more and more generally discredited, is still closely adhered to by many authors and investigators. It is generally conceded that the vast majority of keloids develop from pre-existing scar tissue, usually the result of some evident form of traumatism. Not every trauma, even in predisposed individuals, is necessarily followed by keloid, and in many instances keloids develop on areas which have not been the seat of any manifest injury or cicatricial change. This clinical observation has led to the arbitrary division of keloid into true, genuine, spontaneous or idiopathic, on the one hand, and false, spurious, traumatic or cicatricial, on the other. Repeated efforts have been made from time to time to strengthen this clinically empiric division by a differential histopathology, based chiefly on such gross characters as its deep or more superficial origin and location; the preservation or absence of the overlying papillæ, elastic fibers, hair follicles and glandular structures; the firm fibrous or loose cellular character of the growth; the arrangement and distribution of the fibrous bundles; vascular and other changes. Similar studies and investigations have led to a differentiation of false keloid from hypertrophic scar, and the latter from the ordinary depressed scar. Lack of unanimity of clinical opinion and uniformity of pathologic results have led to somewhat divergent views on the subject. The two latest, and in many respects most exhaustive and complete researches on the subject by Max Joseph[1] and Tschlenow[2] take grounds adverse to each other on many of these important points.

Those who oppose the division of keloid, on clinical grounds, into true and false, or spontaneous and cicatricial, maintain that traumatism plays the predisposing though imperceptible rôle (pin-prick, mosquito-bite, scratch effects from seborrheic eczema, etc.) in every case. This assumption is as difficult to prove as to disprove, and is manifestly more arbitrary and less empirical in character than the converse proposition. The remaining clinical features are sufficiently identical to warrant a classification on purely histopathologic grounds. For the purpose of reaching a closer knowledge and a possibly clearer conception of the points of controversy in the keloid question, I have made a comparative histologic examination of seven cases of spontaneous keloid and three cases of false keloid; for a comparative study of general fibrous tissue, in its relation to false and true keloid, I have added one case of soft simple fibroma, two cases of hypertrophic scar, two of atrophic scar, two of scleroderma and two of macular and striated atrophia cutis.

The following, in brief, is the clinical history and description of the cases which enter in the histologic consideration of the paper:

CASE HISTORIES

Case 1.—*False Keloid.*—L. H., negro, aged 30, received an incised wound 1½ inches long over the left arm, midway between shoulder and elbow, in 1897. The wound was sutured, healed by first intention, but promptly became the site of a keloid. In 1900 the keloid, which was elliptical in outline with sharply circumscribed but sloping borders, with its surface transversely traversed with numerous fine rugæ, measured 4 inches in length, 1 inch in breadth, and about ¼ inch in height. Two short "runners" extended from one end and the middle of the lower border, and several isolated nodules were present over the site of the old stitches. The patient presented himself in March, 1909; the keloid in the past nine years had undergone very slight change. The extirpated extremity became the site of a fresh recurrence, in the form of a bifurcated rounded thickened mass. The central portion had undergone an appreciable degree of spontaneous involution. The borders had not enlarged or encroached to any marked degree on normal new areas in the past nine years.

---

* Read in the Section on Dermatology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

* This paper is accompanied by twenty illustrations, of which only Figures 1-9 and 17-19 appear in The Journal. All appear in the Transactions of the Section and in the author's reprints.

[2] Tschlenow: Dermat. Ztschr., 1903, x, 120.

Case 2.—*False Keloid.*—Mrs. S. J., aged 33, full-blooded negress, was cut in 1896 over the middle of left cheek just below the ear, and the wound healed by first intention. It promptly became the site of a keloidal scar, which in 1901 was firm in consistence, rounded and cylindrical in outline; the surface was covered with characteristic rugæ. Several long, characteristic runners extended from the anterior extremity.

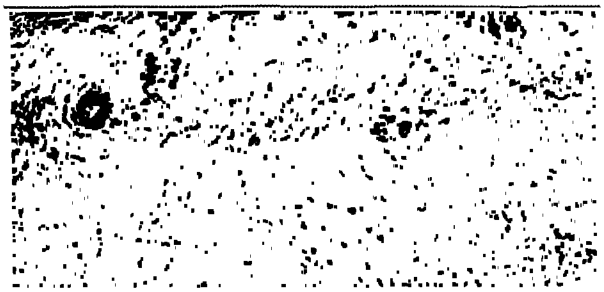

Fig. 1.—False keloid taken from Case 1.

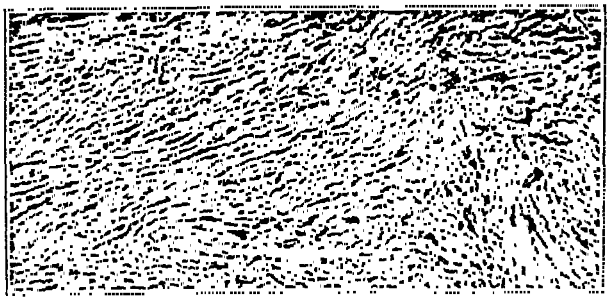

Fig. 2.—False keloid taken from Case. 2.

Case 3.—*False Keloid.*—L. S., aged 18 years, referred by Dr. Bronson of New York, developed several small keloids on the chest from burns incurred in pouring hot tea. The keloids were surgically excised and the resulting incisions, which healed by first intention, together with the stitch holes, became the site of characteristic keloids. Two of these were again extirpated on May 27, 1907.

Case 4.—*True Keloid.*—Mrs. A. J. M., aged 26, developed a spontaneous keloid on the sternum at the age of 15, which was surgically removed by a New York physician in 1907, followed by union with first intention. Recurrence promptly ensued; I extirpated the recurrence on May 16, 1907, within several months of the time of the first operation, and successfully withheld further recurrence by means of ten *x*-ray sittings. On March 5, 1909, on the occasion of a requested visit, the original site of the keloid was occupied by a smooth, white, depressed and scarcely perceptible scar.

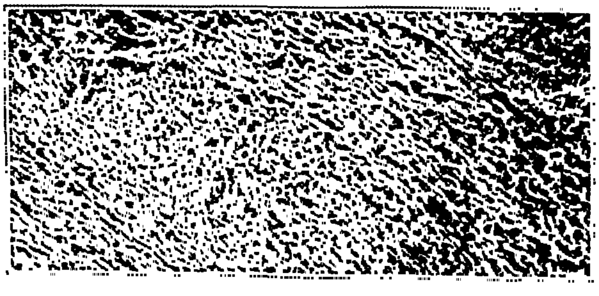

Fig. 3.—False keloid taken from Case 3.

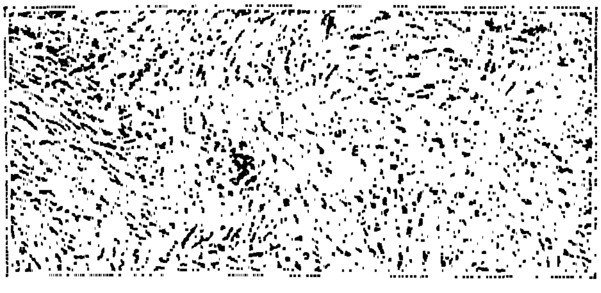

Fig. 4.—True keloid taken from Case 4.

Case 5.—*True Keloid.*—Mr. A. I., aged 62, developed a spontaneous keloid on the left chest near the sternum, the size of a large butter bean, of several months' duration. It was firm in consistency, pinkish in color, non-sensitive to touch or pressure, and free from subjective symptoms, save mild itching. The center was round and elevated, borders sloping and well defined, and surface faintly wrinkled. The lesion was excised January 28 and after eight *x*-ray exposures, no recurrence followed.

Cases 6, 7, 8 and 9.—*True Keloids.*—All spontaneous and of idiopathic origin, of varying duration, one of which was situated on the chest, one on the thigh and the two remaining on the forearm. All were very small, varying from a shot to a bean in size. Surgical extirpation with *x*-ray after-treatment, was not followed by recurrence in a single instance.

Case 10.—*Simple Fibromata.*—Miss C. N., aged 38, presented two small tumors, over the posterior aspect of each arm near the shoulder; the left one, which was about the size of a marble, soft in consistency and somewhat pedunculated, resembled clinically a molluscum fibrosum. The overlying skin was normal in appearance. Its duration was about two years, and its origin spontaneous and non-traumatic in character. The larger lesion was removed Feb. 14, 1909, and the smaller Feb. 21, 1909. A keloidal bluish-red, firm, elevated cicatrix formed at the site of each incision on May 7, 1909, and has already shown a marked tendency to subside under *x*-ray therapy. The histologic structure of both lesions was essentially pure fibrous connective tissue.

Case 11.—*Hypertrophic Scar.*—Miss L. R., aged 26, suffered in girlhood and early youth [illegible] uberculous glands of the neck, which [illegible] the resulting ulcerations became the seat of numerous rough, irregular, hypertrophic scars. Numerous dense, heavy ridges coursed over the affected scars. No active inflammation had been present for the past six or seven years. In 1901 a portion of the most disfiguring area was carefully excised and replaced by a Krause flap.

Case 12.—*Atrophic Scar.*—Mrs. W. B., aged 27, had incurred severe and extensive disfigurement at the hands of a self-styled dermatologist, who applied acid too freely, in July, 1904, for the removal of some facial moles. The deeply depressed cicatrices were extirpated Nov. 7, 1904.

Case 13.—*Hypertrophic Scar.*—Mrs. D. C., white, aged 28, incurred a severe disfiguring hypertrophic cicatrix from the removal of a mole on right of the chin some two years prior to the extirpation, on June 6, 1907.

Case 14.—*Atrophic Scar.*—Mr. H. C. D., aged 52, incurred a smooth, firm, hard cicatrix on the lower lip as a result of an application of arsenic paste for epithelioma some five years prior to the extirpation, which was made on July 11, 1906, to relieve a slight amount of cicatricial irritation.

Case 15.—*Scleroderma.*—A man, aged 50, had multiple circumscribed patches of scleroderma, distributed over the trunk and extremities, of two years' duration.

Case 16.—*Morphea.*—A young girl of 17 had a circumscribed patch of morphea, on the forehead, of six months' duration.

Case 17.—*Macular Atrophia Cutis.*—An unmarried woman of 30 had white spot disease, situated around the base of the neck and upper aspect of the chest.

Case 18.—*Striated Atrophia Cutis.*—A young man of 22 had striated atrophia cutis of several years' duration, abundantly distributed over trunk and extremities.

PRESERVATION OF PAPILLÆ

The clinical observation that many keloids develop from scar tissue, coupled with the fact that papillæ are prone to be destroyed and absent in a cicatrix, has led Kaposi,[3] Warren,[4] Langhans,[5] Joseph, Neumann,[6] Ravogli,[7] Schwimmer[8] and others to differentiate true and false keloid on this basis. Joseph maintains that this observation, original with Warren, must remain a fundamental distinction. Unfortunately, if the basis for this distinction were rational in character, it would fail to hold good for two obvious reasons. First, ordinary scar tissue need not be permanently devoid of papillæ; and, second, papillæ, even when originally present, are prone to disappear in any form of deep-seated new growth, from pressure or distention atrophy.

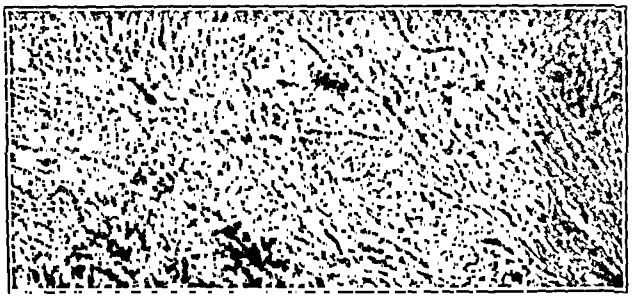

Fig. 5.—True keloid taken from Case 5.

The papillæ were entirely preserved in Case 1 (false keloid), Cases 5, 6, 7, 8 and 9 (true keloid) and in Cases 11 and 13 (hypertrophic scar); they were absent in Case 4 (true keloid) and Case 12 (atrophic cicatrix).

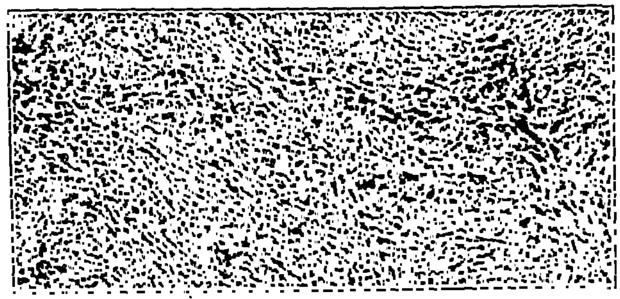

Fig. 7.—True keloid taken from Case 7.

Papillæ were absent in Cases 2 and 3 (false keloid) over areas where the growth reached to and pressed closely on these structures and were normally preserved so long as they remained separated by a comparatively narrow margin of normal connective tissue.

ENCAPSULATION AND LOCATION

It is maintained that true keloid has a deeper origin (Kaposi, Schütz,[9] Goldmann,[10] Joseph and others) in contrast to the more superficial location and development of false keloid, and is surrounded and separated from the overlying papillæ by a well-defined capsule (Joseph and others) of normal connective tissue.

Cases of false keloid (Nos. 1 and 3) and true keloid (No. 4) had a superficial location, and were surrounded with a fairly well-marked capsule of connective tissue, whereas true keloids (Cases 5 and 8), with a similar location, were without a well-defined capsule. False keloid (Case 2) had a deep location and a well-defined capsule, and true keloids (Cases 6, 7 and 9), with a similar location, were devoid of capsules. True keloid (Case 8), as already stated, possessed a superficial location and no encapsulation. The lesion in this case, relatively the smallest in size and the one of shortest duration, was situated on the forearm. Serial sections were made and the point of origin, as nearly as could be determined, was the fibrous envelope of a hair follicle. The orifice of the follicle in question was preserved; the remainder possessed but a semblance of its former structure, and was encompassed by bundles of fibrocellular tissue which somewhat preserved in their primary distribution the general contour of the follicle and its obliterated sebaceous gland; innumerable smaller bundles branched from the sides of the structure, intertwined or curled on themselves, and extended laterally in all directions and in the main parallel to the surface of the skin.

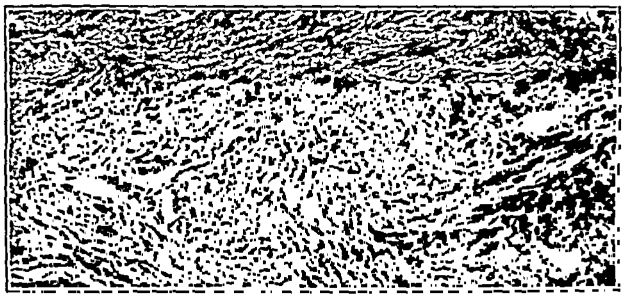

Fig. 6.—True keloid taken from Case 6.

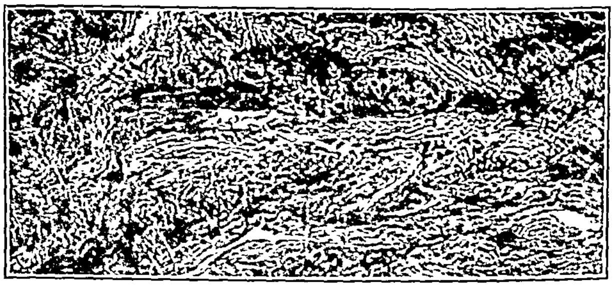

Fig. 8.—True keloid taken from Case 8.

PRESERVATION OF ELASTIC FIBERS

Much significance has at times been attributed to the presence or absence of elastic fibers in keloids. Their constant absence in keloid, and repeated presence in regenerated scar tissue, of sufficient standing, have induced some authors (Joseph, Meissner,[11] Kromeyer) to maintain that histologic differentiation is tenable on their presence or absence. Furthermore, the atrophic character of scar tissue has been attributed in a few instances to the restraining influence of elastic fibers, when present, and the hypertrophic character, when absent.

[11] Meissner: Dermat. Ztschr., iii, 182.

Elastic fibers were constantly absent except in Case 10 (simple fibroma) and Cases 15 and 16 (multiple patches of circumscribed scleroderma and morphea). They were present at the immediate confines of the growth in many instances, namely, Cases 3, 4, 7, 11, 13 and 17. In Case 9 (small true keloid of forearm) they were abundantly present between the growth and the epidermis. They were uniformly absent in true and false keloid, and in atrophic and hypertrophic scar tissue, irrespective of their duration and development. Their presence in Case 10 (simple fibroma) did not check the elevation and hypertrophic development of these lesions, which were slightly pedunculated, and their absence was constant in every atrophic cicatrix and lesion except in Case 10 (soft fibroma), already mentioned, and Cases 15 and 16 (multiple circumscribed scleroderma).

ARRANGEMENT AND DISTRIBUTION OF THE FIBROUS BUNDLES

It is maintained (Joseph, Warren, Kaposi, Berliner[12] and others) that in true keloid the dense bundles of fibrous tissue possess a more or less regular and systematic distribution, and are arranged in the main parallel to the surface of the epidermis. This arrangement was observed in only one case of true keloid (Case 4), and only as regards the lower strata of fibers. The arrangement, however, was observed in false keloid (Cases 2 and 3). In Case 2 the lower strata were irregularly interlaced; and in Case 3 masses of bundles were separated by fibrous septa. The interlaced character of the bundles, which is commonly attributed to false keloid, was manifest only in Case 1. A very irregular indefinite arrangement of the fibrous bundles, in which they curled on themselves and branched and crossed each other at random, occurred in Cases 5, 6, 7, 8 and 9 (true keloid), in Case 10 (simple fibroma) and Cases 15 and 16 (scleroderma). Bundles were evenly arranged and parallel to the surface of the epidermis in Cases 11 and 13 (hypertrophic scar) and in Cases 12 and 14 (ordinary irregular and depressed scars).

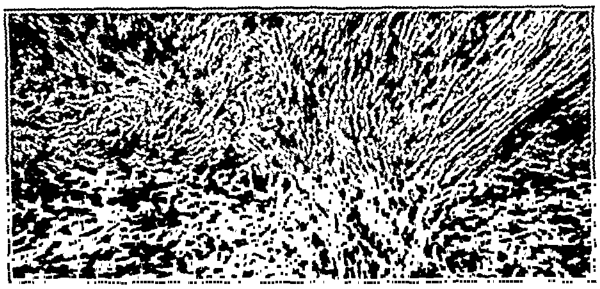

Fig. 9.—True keloid taken from Case 9.

FIBROCELLULAR CHARACTER

It is sometimes maintained (notably by Babes[13] and Joseph) that true keloid can often be histologically differentiated from false by its more cellular character, the shortness of its fibers, which are frequently reduced in length to mere spindles, the relatively larger nuclei, and by the presence of endothelial cells and remnants of partially obliterated blood vessels. It is conceded that there are marked variations between the extremes in both classes: that the variation in cellular and fibrous character depends, to some extent, on the duration of the process; the more recent the process the richer its cellular character. These are the chief points which are embraced in this histopathologic differentiation. All the specimens were similarly prepared and stained, and the most characteristic area of each was photographed under the same magnification. The photographic records confirmed the theory that a histologic cellular differentiation was quite impossible. False keloids (Cases 1 and 2) were rich in cells, with large oval distinct nuclei and rather short well-defined spindles; the same structure was approximated in the ordinary scar following the removal of a mole, in Case 13, and in true keloids (Cases 7, 8 and 9). In false keloid (Case 3) the structure was almost purely fibrous in character. The structure was almost purely fibrous in the remaining cases of true keloid, with a somewhat varying predominance of interspersed spindle-shaped cells, with small and indistinct nuclei. True keloid (Cases 4, 5, 7, 8 and 9) showed a somewhat more cellular and in Case 6 an almost pure fibrous structure. An absolute differentiation of false from true was not possible and a deceptive similarity of structure attained in all the cases of true and false keloid, and hypertrophic and simple scar. Hypertrophic scar (Case 11) and ordinary scar tissue (Case 13) were purely fibrous or almost purely fibrous in structure. The case of ordinary scar following application of arsenic paste was rather cellular in type. The duration and long standing of the process seemed to exercise little influence in determining the cellular or fibrous character of a lesion, cases of five to twelve years' or longer duration, being often more cellular in type than similar lesions of relative short (months) duration.

In only two instances (Cases 15 and 16, scleroderma) did the fibrous tissue approximate normal collagenous connective tissue in structure and appearance, and assumed its peculiar undulating and wavy character. Normal connective tissue in its characteristic state was abundantly present at the confines of most of the lesions examined. The lesions in white spot disease and striæ atrophicæ were wavy and undulating in appearance, but failed to show the peculiar reticulated network of interlacing fibrils constantly manifest in normal connective tissue, and which stamps it with an unmistakable and characteristic histologic individuality.

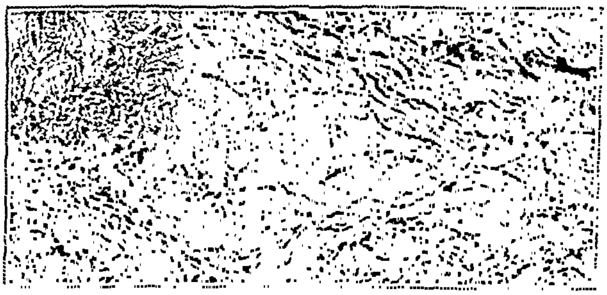

Fig. 17.—Simple fibroma.

PRESERVATION OF HAIR FOLLICLES, SWEAT AND SEBACEOUS GLANDS

Hair follicles undergoing obliteration were observed in only two cases (Nos. 6 and 8). Both were small spontaneous keloids of relatively short duration. Sweat glands in a fair state of preservation were found in Case 10 (soft simple fibroma). Normal or almost normal hair follicles were found conserved in close proximity to the growths, in false keloid (Cases 1 and 3) and spontaneous keloid (Cases 6 and 7); sebaceous glands in proximity to false keloid (Case 1); and sweat glands in proximity to false keloid (Cases 1 and 3), and spontaneous keloid (Case 6). In false keloid (Case 1) sweat glands were normally preserved below the keloid.

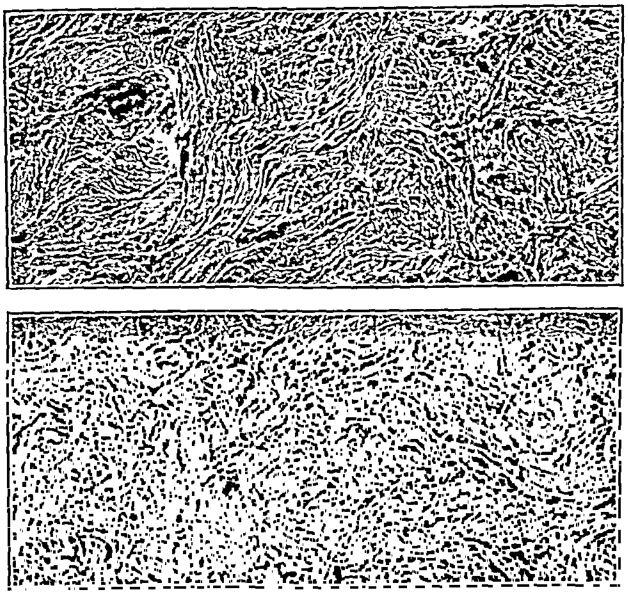
EXTENSION ALONG BLOOD VESSELS

The careful study and examination could in nowise confirm the original and amply affirmed observation of Warren (Collins, Unna,[14] Kaposi, Joseph, Neuermann, Crocker,[15] Freund[16] and others), that the extension of keloid can be readily traced along the course of the adjacent blood vessels, and that the latter were pathologically altered and surrounded with plastic exudate for some distance from the pathologic area. Nearly all the specimens showed vascular congestion and round-cell infiltration about the smaller capillaries, but not more than one would reasonably expect to encounter in any pathologic process of similar character and proportions. Some thin-walled, newly formed capillaries were observed in the body of many of the growths, but other vascular changes appeared to be purely inflammatory and secondary in character, due to direct involvement and extension on the part of the growth, and not *vice versa.* Growth and extension seemed to occur by reduplication and multiplication of the pathologic cell, and mitosis and cell division and transition to fibrous tissue was a matter of common observation. The early and marked involvement of hair follicles in several cases, and the apparent development of the small spontaneous lesion in Case 8, as observed from serial sections, have led me to believe that the fibrous envelope of glandular elements is a more probable cause than the fibrous coats of blood vessels. This is also in a measure strengthened by a confirmation of Thorn's observation[17] that keloid is free from involuntary muscular fiber. The tendency for keloid to become self-limited in its clinical growth, and not to involve the deeper subcutaneous structures, also speaks strongly against a vascular origin and an extension along blood vessels. The involvement of blood vessels seems to be not a primary process, but a secondary one due to the dirct independent extension of the body of the growth proper. In this way the blood vessels become invaded and involved, in the same manner as the hair follicles, sudoriferous and sebaceous glands and other specialized structures of the skin.



Figs. 18 and 19.—Ordinary collagenous connective tissue in the neighborhood of two cases of keloid.

SUMMARY

Briefly recapitulated and summarized, the essential observations gleaned from the histologic study of the enumerated cases are as follows:

1. The preservation of the *papillæ* does not differentiate true or spontaneous keloid from false keloid or from hypertrophic and atrophic scar tissue. They were found absent in spontaneous keloid and preserved in false keloid and found regenerated in cicatricial tissue. In this respect the claims of Kaposi, Warren, Joseph, Ravogli, and others are refuted.

2. A deep location does not differentiate true keloid from false. Three out of six cases of true or spontaneous keloid possessed a superficial location; and one case out of three of false keloid had a deep location. The claims of Kaposi, Joseph, Schütz and Goldmann are in this respect refuted.

3. Preservation of the capsule was not indicative of true keloid; most of the cases of spontaneous keloid were devoid of well-defined capsules, and all of the false cases possessed fairly well-defined capsules.

4. Absence of elastic fibers does not differentiate true keloid from false, or either of these from cicatricial tissue. It was found uniformly absent in all of these structures. Its absence does not serve to differentiate keloids from fibromata in general if a soft simple fibroma comes into that category. Elastic fibers were also found preserved in the fibrous structures of two cases of scleroderma. I share the views of Tschlenow as opposed to those of Joseph, Kromeyer, Meissner and others on the futility of this histologic differentiation. No regeneration of elastic fibers in scar tissue was observed in any of the cases.

5. The absence of elastic fibers is not an etiologic factor in the hypertrophic character of keloid as maintained by Ravogli and Goldmann. Their absence was noted in the depressed lesions of striated and macular atrophy and depressed cicatrices, and their presence in a simple soft fibroma did not inhibit the hypertrophic character of the gross lesion.

6. The contention of Warren, Kaposi, Joseph and Berliner, that the fibrous bundles of true keloid preserve in the main a longitudinal arrangement, parallel to each other and to the surface of the skin, in contradistinction to the interlaced character of false keloid, is controverted in five out of six cases of spontaneous keloid, and in two out of three cases of false keloid. The interlaced character was observed in simple soft fibroma and scleroderma, and the parallel arrangement was observed in ordinary scar tissue.

7. A differentiation of true from false keloid, and the former from hypertrophic and atrophic scar tissue, as maintained by Dieberg,[18] Kaposi, Schimmer, Joseph and others, was not tenable. Joseph's contention that old keloid is more fibrous and new keloid more cellular could not be confirmed. A deceptive non-differentiable similarity of structure obtained in true and false keloid, and hypertrophic and simple scar tissue. All these structures could be easily differentiated histologically from normal collagenous connective tissue, which was present in close proximity to the majority of the examined lesions.

[16] Freund: Arch. f. Dermat. u. Syph. (Festschr. Kaposi), 1900.

[17] Thorn: Arch. f. klin. Chir., 1896, li, 619.

[18] Dieberg: Deutsch. Klinik, 1852, No. 33.

8. A deceptive similarity in histologic structure exists between scleroderma and normal collagenous connective tissue.

9. The differentiation of true from false keloid by the preservation of hair follicles and glands, which are neither pushed aside nor subject of pressure atrophy (Volkmann,[19] Joseph and others) was negated. The relatively few glands which were encountered occurred in equal measure in false and true keloid, and were pushed aside and subject to atrophic changes.

10. No origin could be traced to the adventitia or primary extension along the blood vessels of the corium, as maintained by Collins, Joseph, Unna, Kaposi, Neumann, Crocker, Wilms,[20] Dénériaz,[21] Freund and others, and denied by Thorn and Reiss.[22] The apparent origin in one case from a hair follicle, and the marked and prompt involvement of the glandular structures leads me to share the views of Berliner and Kirsch,[23] of the probable origin of keloid from these structures.

11. There seems to be as little basis for the assumption that trauma must play the causative rôle in every case of keloid (Jadassohn,[24] Schütz, Tschlenow, Besnier,[25] Barthelemy Hutchinson,[26] Unna and others) as that of attempting a successful histologic differentiation on the same grounds (Kaposi, Warren, Langhaus, Ravogli, Neumann, Schwimmer, Joseph and others). An idiopathic or spontaneous etiology must be conceded to some of the cases of keloid, as long as these terms find a general acceptance for other affections.

12. A differentiation of true and false keloid is not possible on clinical or histologic grounds; the differentiation of keloid in general from scar tissue is not possible on histologic grounds. Keloid and scar tissue can be histologically differentiated from normal collagenous connective tissue.

ABSTRACT OF DISCUSSION

Dr. W. A. Pusey, Chicago: It was grateful to my desire to see generalizations in our groups of dermatoses, to hear the opinion expressed by Dr. Heidingsfeld that there is no essential difference histologically between hypertrophic scars and keloid; that is in the interest of simplification and decidedly in the direction that we hope dermatology will go. I am strongly of the opinion that there is no essential difference between hypertrophic scars and keloids, the difference being one simply of degree.

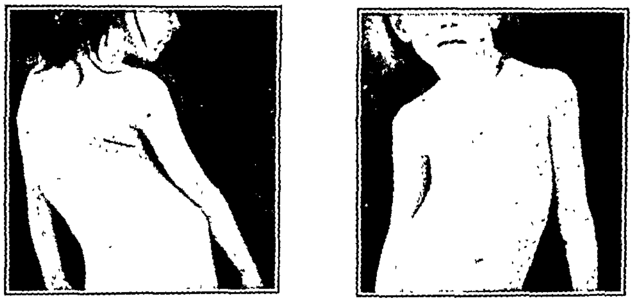
Dr. Maximilian Herzog, Chicago: About two years ago I published the report of cases of multiple keloid in Chinamen who were addicted to the morphin habit. I also at that time expressed the opinion that there was no essential difference between the so-called idiopathic and the acquired or traumatic keloid. In the cases I reported, the keloidal growths all followed the slight traumatism inflicted by the puncture of the hypodermic needle. Histologically, it is impossible to differentiate sections from the so-called idiopathic and from traumatic keloids. I can therefore fully subscribe to the opinion expressed by Dr. Heidingsfeld in his paper.

PERSISTENT THORACIC SINUS FOLLOWING EMPYEMA

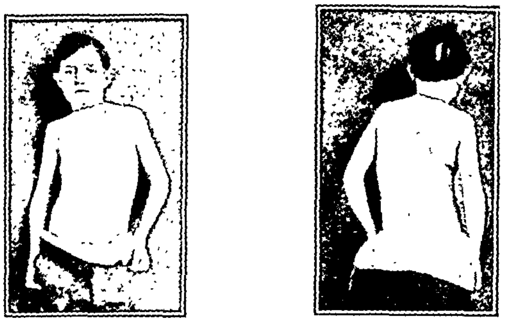
A REPORT OF FIFTEEN CASES TREATED BY DECORTICATION OF LUNG AND THORACOPLASTY *

CHARLES N. DOWD, M.D.
Attending Surgeon to the General Memorial Hospital and to St. Mary's Free Hospital for Children
NEW YORK

The persistent sinuses which occasionally follow pyothorax have long brought annoyance and perplexity to surgeons and ill health and disappointment to patients. Thoracoplasty has usually been tried for their relief, with varying degrees of success, and since Fowler[1] in 1893 and De Lorme[2] three months later, dissected away the constricting pulmonary pleura their operation of "lung decortication" has attracted considerable attention. This operation has become rather more firmly established on the continent of Europe than here and has been used by many surgeons. Bergeat[3] has recently made a very complete report of the subject from Dr. Sick's clinic in Hamburg, where the Schede operation was first elaborated: lung decortication was here done seven times in the treatment of twenty-one cases of persistent empyema, and it was done more commonly in the later than in the earlier cases. It was always done in conjunction with more or less resection of the chest wall and its value is appreciated. Jordan,[4] Kurpjurorit[5] and Bayer[6] may be mentioned among the others



Figs. 1 and 2.—Extreme deformity following lung collapse of two years' duration, Case 11.



Figs. 3 and 4.—[illegible] six weeks after an operation for relief of [illegible] Case 13. The extreme lung compression [illegible] pyema of two months' duration. The extreme chest contraction followed the failure of the lung to expand.

glands in proximity to false keloid (Case 1); and sweat glands in proximity to false keloid (Cases 1 and 3), and spontaneous keloid (Case 6). In false keloid (Case 1) sweat glands were normally preserved below the keloid.

EXTENSION ALONG BLOOD VESSELS

The careful study and examination could in nowise confirm the original and amply affirmed observation of Warren (Collins, Unna,[14] Kaposi, Joseph, Neuermann, Crocker,[15] Freund[16] and others), that the extension of keloid can be readily traced along the course of the adjacent blood vessels, and that the latter were pathologically altered and surrounded with plastic exudate for some distance from the pathologic area. Nearly all the specimens showed vascular congestion and round-cell infiltration about the smaller capillaries, but not more than one would reasonably expect to encounter in any pathologic process of similar character and proportions. Some thin-walled, newly formed capillaries were observed in the body of many of the growths, but other vascular changes appeared to be purely inflammatory and secondary in character, due to direct involvement and extension on the part of the growth, and not *vice versa.* Growth and extension seemed to occur by reduplication and multiplication of the pathologic cell, and mitosis and cell division and transition to fibrous tissue was a matter of common observation. The early and marked involvement of hair follicles in several cases, and the apparent development of the small spontaneous lesion in Case 8, as observed from serial sections, have led me to believe that the fibrous envelope of glandular elements is a more probable cause than the fibrous coats of blood vessels. This is also in a measure strengthened by a confirmation of Thorn's observation[17] that keloid is free from involuntary muscular fiber. The tendency for keloid to become self-limited in its clinical growth, and not to involve the deeper subcutaneous structures, also speaks strongly against a vascular origin and an extension along blood vessels. The involvement of blood vessels seems to be not a primary process, but a secondary one due to the dirct independent extension of the body of the growth proper. In this way the blood vessels become invaded and involved, in the same manner as the hair follicles, sudoriferous and sebaceous glands and other specialized structures of the skin.

in the series
essive deformity
as taken from the

who advocate the method. Many French surgeons have advocated the procedure since the publication of De Lorme's classical article.

A review of the American surgical literature of the last ten years shows fewer contributions to the subject than one would expect, although Ransohoff[7] has contributed a very practical method of liberating the pulmonary pleura, and Ferguson[8] has recorded seven cases in which he dissected away the sinus walls.

CASES ON WHICH THIS REPORT IS BASED

Within the last nine years I have employed the procedure coupled with thoracoplasty in fifteen cases, all but one of them in St. Mary's Free Hospital for Children. The average age of the St. Mary's Hospital patients was 5½ years; the fifteenth patient was an adult. In seven of these patients the primary empyema operation had been done elsewhere. The remaining eight persistent sinuses occurred among a total of 186 cases of empyema, thus indicating an expectation of about 4 per cent. of such sinuses in the empyema cases as they are referred to us in New York. The average lapse of time between the primary opening of the chest and the secondary lung decortication and thoracoplasty was fifteen months.

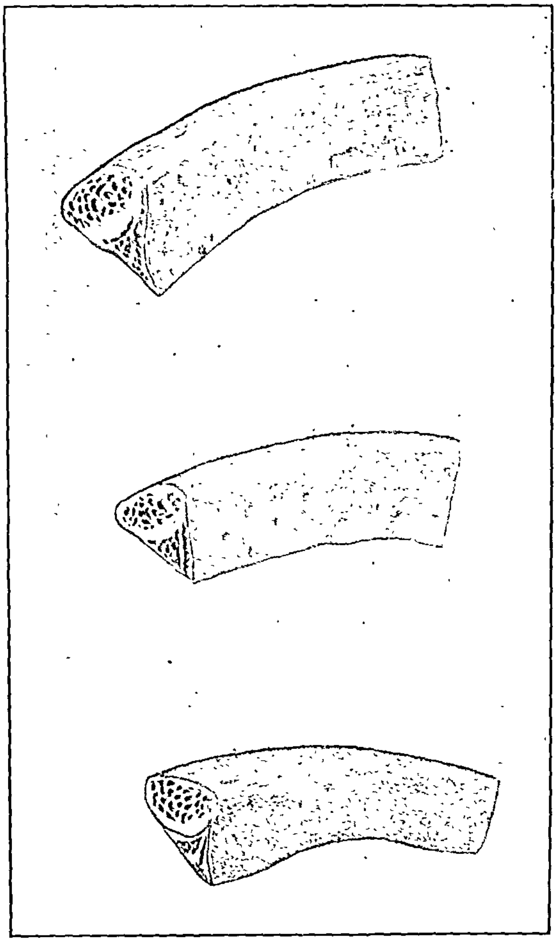

Fig. 5.—Rib compression and formation of new bone on inner surface of rib, due to Nature's effort to bring the chest-wall into apposition with the collapsed lung, Case 13.

Un TYPE OF CASES SUITABLE FOR OPERATION

15. Crock
16. Freund nt always been easy to determine when an
17. Thorn: A ld be advised for an unhealed pyothorax.

Sinuses which are accompanied by little deformity or suppuration may be treated for long periods without operation and will frequently close and leave very good lung function. Ochsner's recent report[9] of fourteen such cases treated by the aid of Beck's bismuth paste is very instructive, and his results are most satisfactory. In the selection of cases suitable for such treatment one may well remember the possibility of bismuth remaining as a foreign body within the chest cavity and follow Ochsner's example in applying the method only to cases with well formed sinuses.

On the other hand, sinuses which are coupled with excessive deformity and disturbing suppuration should be treated by operation while there is still a possibility of obtaining lung expansion; delay for them may be disastrous. Failure of lung expansion gives the key to the situation.

CHANGES WHICH ACCOMPANY PERSISTENT LUNG COLLAPSE

When the lungs fail to expand a distressing deformity results. Nature apparently abhors an empty chest. Figures 1 and 2 depict an extreme instance of this deformity; it occurred during the two years' non-operative treatment of a persistent empyema sinus. The original empyema operation had consisted of the removal of a short piece of the eighth rib in the posterior axillary line. The deformity shown in Figures 3 and 4 occurred within six weeks after a similar operation for extreme, neglected pyothorax.

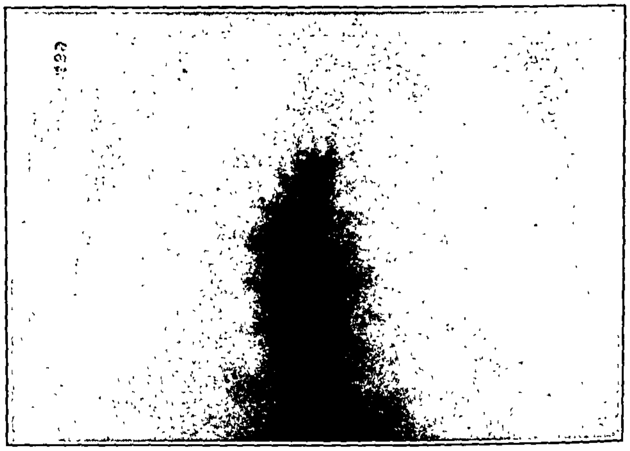

Fig. 6.—Radiograph showing the chest contraction and lateral spinal curvature in Case 13.

The changes in these cases may be summarized as follows:

1. Position of shrunken lung is against the mediastinum in the upper part of the chest.
2. There is lateral curvature of spine with concavity toward the affected side.
3. There is crowding of ribs on each other, so that the intercostal spaces are obliterated, their vertical diameters are lessened, and a new deposit of bone is found on their inner sides (Fig. 5).
4. There is bulging of diaphragm into the chest and against the lower ribs, the apposition sometimes including the sixth rib.
5. There is formation of firm exudate, which becomes so incorporated with the pleura that it seems like a pleural thickening. This is much thicker on the costal than on the pulmonary pleura.

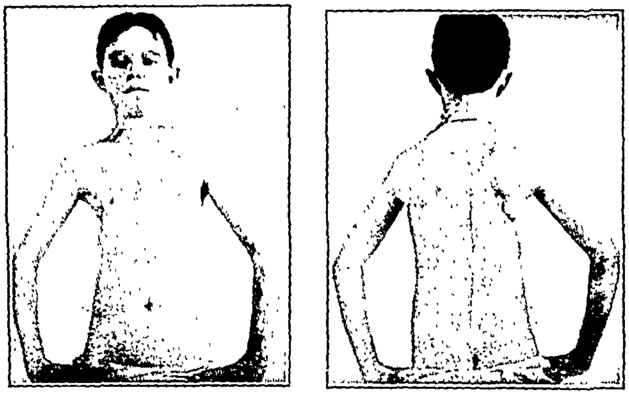
Surg., April, 1906.
Surg. Assn., 1909.

[9] Ochsner: Ann. Surg., July, 1909, p. 151.

6. There is formation of a firm walled sinus which leads from the opening in the chest wall to the apex of the pleural cavity, usually about large enough to hold one finger and sometimes much larger.

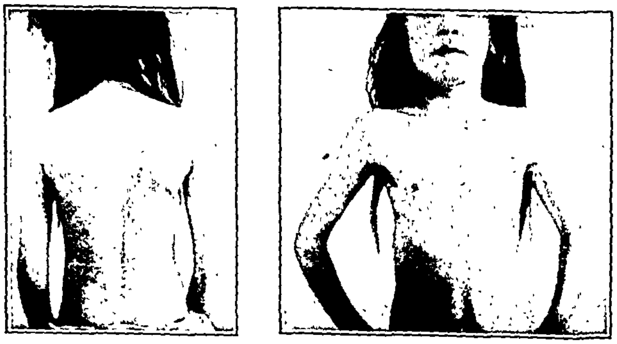
METHOD OF OPERATION

Ether anesthesia was used, the patient lying on the sound side. "Orientation" incision was made about the sinus opening, with resection of 3 or 4 inches of the rib above and the one below it, thus learning the size and direction of the sinus. The incision was then carried upward, usually in the anterior axillary line to the third rib. The ribs were divided and suitable portions removed, usually ½ inch from the second or third, 4 to 6 inches from the tenth, and corresponding pieces from the intermediate ones. Sometimes much less was taken away.



Figs. 7 and 8.—Result in Case 13, two years after operation.

With suitable retraction an excellent view of the sinus is thus obtained. A longitudinal incision is then made through the upper part of the sinus wall until the lung is reached. At this stage of the procedure the patient is allowed so nearly to emerge from the anesthesia that he will cough, when the lung usually bulges into the incision. The membrane is then separated from its surface over as large an area as is practicable and removed. In most of these cases a strip 2 or 3 inches long and from 1 to 2½ inches wide has been removed. This represents somewhat more than the pulmonary portion of the sinus lining. The chest wall was nearly brought together by strong sutures and a drain or suction tube inserted in the unclosed part.



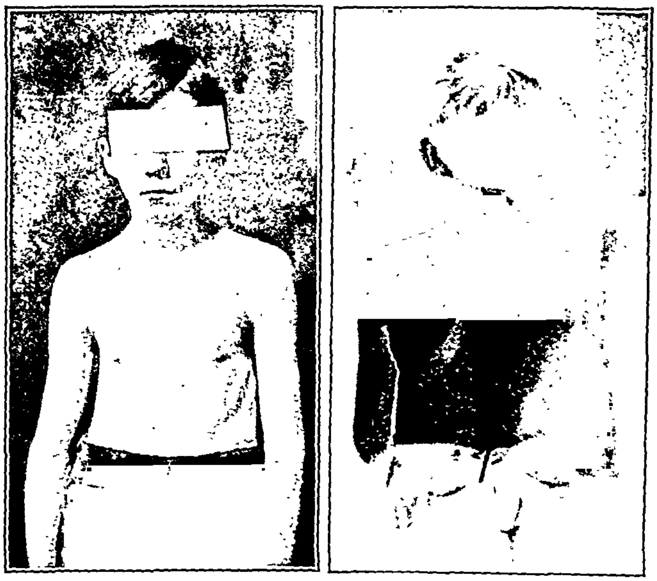
Figs. 9 and 10.—Result in Case 9, four and a half years after operation.

VARIATIONS

The amount of chest wall which was removed differed materially in the various cases and was dependent on the likelihood of gaining lung expansion. In one of the cases so little was resected that the operation could hardly be called thoracoplasty, and the lung expanded so as to fill the chest. The degree of chest-wall resection is indicated in some of the accompanying illustrations, which show the final results. In three of the cases in which additional operations were necessary, the lung was found collapsed against the mediastinum and could not be made to expand; it looked dark and spongy and had none of the pinkish inflated appearance which had been noted in other cases. On incising it, air whistled through it, but it showed no tendency to expand. For such cases Ferguson dissects away the fibrous lining of the apex and side walls of the sinus, for the purpose of obtaining an extensive surface for the production of new granulation.

AFTER-TREATMENT

Persistent and continued blowing on James' (or Wolf's) bottles has been used in every case. Negative pressure by means of Cotton's and other apparatus has been used in two cases. The pneumatic cabinet has not been used.



Figs. 11 and 12.—Result in Case 1, nine years after operation.

Judging from the appearance of the lung when the patient coughs, the writer believes that the expansive power which accompanies forcible blowing is very great; greater than is obtained from the other measures. Early and continued physical exercise is encouraged.

RESULTS

The results of this procedure are very encouraging. Twelve of the fifteen patients are in excellent health at the time of this report, or at the last observation; from a few months to nine years after operation, with varying degrees of chest expansion and chest capacity, and without lateral curvature of the spine. One of these twelve has a small sinus, but this sinus causes so little disturbance that he is unwilling to have anything done for it. One patient having a healed chest and nearly erect carriage lived seven years after the operation and then died of "dropsy." One patient has died of tuberculosis. One patient died a few days after her operation. This was the only operative death in the series and occurred in the patient whose excessive deformity is shown in Figures 1 and 2. She was taken from the

TABULATED ABSTRACTS OF CASE HISTORIES

No.	Age.	Hosp. No.	Side.	Date of primary operation for empyema.	Date of operation for lung constriction, and deformed chest wall.	Date of discharge from hospital.	Remarks.	Results.
1	5	102	L	2/ 8/1900	5/23/1900	7/30/1900	The primary lung compression was excessive; the pus having perforated the chest wall.	Examined March 10, 1909; erect, in good health; a champion tennis player in Van Cortlandt Park; circumference of right side of chest 2 inches less than left; good respiratory power.
2	4	B100	R	8/14/1900	10/25/1900	....	Lung expansion at operation unsatisfactory. Tuberculosis present.	Died Dec. 9, 1900, from tuberculosis.
3	8	C34	L	10/../1897	11/15/1900	2/25/1901	Case complicated by tuberculosis in pleura and axilla. Two operations had been done between October, 1897 and November, 1900. Small sinus persisted till March, 1902 and then healed firmly.	Seen March, 1909; in good health; erect carriage; circumference of left side of chest 1¾ inches less than right; good respiratory murmur.
4	7	287 888	L	4/../1900 ?	4/19/1901 5/ 8/1903	10/ 2/1901 6/23/1903	At both operations very great lung compression. Worse at second than at first.	Enjoyed good health, with chest healed and nearly erect carriage till 1908, then died of "dropsy."
5	4	909	L	1901	5/ 8/1903	7/25/1903	Lung did not expand well after decortication but sinus healed.	Reported in good health summer 1908.
6	3	1054 1209	L	12/17/1902	4/17/1903 1/ 4/1904	9/16/1903 1/31/1904	Extreme collapse of lung found at both operations. Good healing obtained.	Seen January 1905 and picture taken; erect and in good health; considerable contraction in left side of chest; good respiratory murmur; sinus firmly healed.
7	28	9988*	L	1899	6/11/1903	7/ 4/1903	Extreme lung collapse. Capacity of chest cavity about Oiii. Lung dark red and showed no tendency to expand.	Letter March, 1909, states "in best of health" working hard and eating and sleeping well; small sinus still present.
8	5	988 1311	L	12/ 4/1902	2/19/1904 2/27/1905	9/15/1904 3/30/1905	Was in country branch of the hospital between the two operations in good health but with small sinus.	May, 1909, in excellent health; erect carriage; sinus healed.
9	6	1529	R	3/21/1904	6/ 3/1904	8/ 4/1904	Sinus large enough to hold two fingers healed promptly. (Within two months.)	Examined Dec. 5, 1908; good health; erect; circumference of left side of chest 1¾ inches less than right; good respiratory murmur and good mobility.
10	6	305 1617	R	9/20/1901	7/ 1/1904	9/15/1904	Diaphragm at about the level of 5th rib. Lung much contracted. Prompt healing after decortication.	Seen winter 1905; in good health; erect.
11	8	1677	R	9/../1902	9/23/1904	9/25/1904	Extreme deformity—see Fig. 1. Lung about 1/6 its normal capacity.	Child removed from hospital by parents and died a few days later.
12	4	3472	R	1/../1907	4/ 5/1907 6/10/1907	7/ 9/1907	Lung extremely collapsed; found with difficulty; expanded after decortication when child coughed.	Seen December, 1908; well nourished; strong; erect; circumference of right chest 1¼ inch less than left; good respiratory murmur; a little later a small sinus opened which healed after operation.
13	12	3587 4739	R	4/ 2/1907	5/16/1907 9/19/1908	8/20/1907 10/10/1908	Empyema of two months' standing before chest first opened; lung could not be felt by finger in chest cavity. Rapidly progressing deformity at time of first decortication; see Fig. 3. Prompt healing, but sinus opened just before second decortication and then healed again.	March 10, 1909; circumference of right side of chest 3½ inches less than left; good respiratory murmur; is erect and in good health; see Figs. 7 and 8.
14	6	4556	R	6/ 2/1908	9/11/1908 3/26/1909	12/20/1908 6/12/1909	Lung extremely collapsed but bulged well on coughing; sinus persisted; another operation followed by good healing.	Report Aug. 1, 1909; good condition; sinus healed.
15	4	5549	R	11/20/1908	2/23/1909	4/14/1909	Lung expanded so well on coughing that ribs were fastened together with hardly any resection.	June 5, 1909; in good condition; erect; good respiratory murmur.

* General Memorial Hospital

hospital by her parents two days after her operation, while doing reasonably well, and died a few days later in her insanitary tenement surroundings.

PROPHYLAXIS

Prompt relief of pyothorax before lung compression takes place is the best way of preventing persistent sinuses. When a chest is opened for empyema an inch and a half of the eighth rib may be removed in the posterior axillary line. The finger may be inserted to remove coagula and to determine the position of the lung. The lung will usually expand at this time if the anesthesia is withdrawn and the patient allowed to cough. If the lung does not expand, adhesions may be very carefully started with the finger.

In the after-treatment, blowing exercises and suction apparatus and active physical exercise are desirable.

SUMMARY

So far as deductions can be drawn from this group of cases, they indicate the following:

1. Persistent thoracic sinus can be cured by decortication of lung and resection of the chest wall in 80 to 90 per cent. of the cases.
2. After operation the patient will not have lateral curvature of the spine.
3. The lung capacity on the affected side will remain much diminished.
4. Nearly all the patients are in good health and are not materially inconvenienced by this restricted lung capacity.
5. The mortality from the operation is probably more than 5 per cent. and less than 10 per cent.

ABSTRACT OF DISCUSSION

Dr. Emil G. Beck, Chicago: Resection of the chest wall for suppurative old sinuses should be reserved for old cases in which all other treatment has failed, as it is a procedure which will cause great deformity. A report from Dr. Ochsner of Chicago was presented before the American Surgical Association recently on fourteen patients who were treated with 33 per cent. bismuth-vaselin paste. Twelve of these sinuses are healed and 2 are much improved. Of my own patients, 13 sinuses were treated with this paste and 11 are closed, 1 patient is continuing the treatment, and 1 died. The latter had first been operated on unsuccessfully, then received this treatment, which also had no effect, and then was operated on again and died shortly after this operation. By this very simple procedure, without risk to the patient, 80 per cent. of these patients can be cured without operation. There is, however, danger of bismuth poisoning, which may be obviated if the physician will watch the cases. I have had but one case in which I saw distinct symptoms of bismuth poisoning and in that case I prevented further absorption by dissolving the paste with warm olive oil and then removing the bismuth. I have also tried as a prophylactic method the injection of a 5 per cent. bismuth-vaselin paste and all the sinuses closed without fever within ten days.

Dr. C. G. Kerley, New York: If there are any other means that would give better results than the methods suggested by Dr. Dowd, I will be glad to know of them. I have used the Bier method and seen it employed in several cases, without any striking results. Vaccine therapy has been used during the past year or two, usually with indifferent results. I have not had much success with the James bottle. It is looked on as a toy. The child will blow vigorously for a few days and then it is difficult to make him use it further. I have had much better results in expanding the lung in the use of different forms of exercise. One of these is carried on by putting a towel around the sound side of the chest, tying the towel or bandage to some stable object, and allowing the child to rest his weight in the towel, thus compressing the sound lung, at the same time breathing deeply in order to bring the diseased lung into action. Giving the child three exercise periods daily of ten minutes each has been followed by surprising success in my cases. Later, any exercise that will make the child breathe deeply is to be advocated.

Dr. Linnaeus E. LaFetra, New York: I have had the same experience with the blow bottle that others report; but there has been devised within the last year or two a little toy pipe with a rubber bag attached at the bowl to imitate a soap bubble. Children take much pleasure in blowing up these rubber bubbles to see how large they can be made. Other rubber bags are made in the form of animals, and much exercise results from using such devices. In the last three years I have seen two of the cases described by Dr. Dowd in which the results are most satisfactory. The lung will expand during the operation when the child coughs or makes a forced expiration.

Dr. Abraham Jacobi, New York: I have had the same difficulties in dealing with fistulas that have been described. The bismuth paste may probably fill up many of these fistulas. I have had fistulas up to eleven inches in length to deal with and I have had to operate after injections of tincture of iodin had failed. I have relied on iodin and it always failed. In the common run of empyema cases no one would think of employing this method, but in bad cases, in which adhesions are great, what would this operation and positive pressure do?

Dr. C. N. Dowd, New York: In my paper I incorporated references to his work and the results of Dr. Ochsner's treatment, and stated there that this method is to be tried before operation is resorted to. One may, however, select the cases in which it is to be used. When used in unsuitable cases, the bismuth has sometimes remained in the chest as a foreign body and has helped to keep the sinus open. When Dr. Beck's method and other methods fail, when the spinal curvature is increasing or has already reached an extreme degree, when expansion of the lung is prevented by its firm fibrous envelope and when the chest contraction is excessive, we have the suitable condition for the operation which I have described, and in certain instances of steadily progressing deformity it may be used before this full deformity has been reached. In the cases here reported, the average lapse of time between the primary empyema operations and the lung decortication was fifteen months—too long a time.

The method has been spoken of as producing deformity. It should, however, be referred to as preventing deformity and restoring the erect posture. The greatest deformity comes from Nature's effort to bring the chest wall into opposition with a collapsed lung. After thoracoplasty and lung decortication the erect posture is regained. This has been noted for years after the Schede operation.

Some form of negative pressure has been used in several of these cases. It can be maintained satisfactorily, but its results have been disappointing. That positive pressure is effective is shown by having the patient so lightly narcotized that he will cough and expand the lung at the time of the primary operation and later the toys to which Dr. Kerley has referred and the blow bottles are very useful. The special field of the pneumatic cabinet seems to be in other conditions than empyema. The increased pressure which is ordinarily used is not greater than the difference between the atmospheric pressure in the lower and upper floors of a high building and this is not sufficient to overcome the adhesions of a confined lung—not so great as the coughing or toys or bottles give. I know of one fatality which occurred in its use which would probably not have occurred had the anesthetist been in satisfactory communication with the operator.

Care of Children.—In education and religion, and in the principles of good citizenship, the child is the key to the problem. If we are to have literary men and women we must begin with children. By far a large majority of those noted for their strength of character have formed that character before 16 years of age. The best citizens are those who have instilled into their minds the principles of good citizenship during childhood.—Marion Hull, in *Annals of Medical Practice*.

CEREBROSPINAL SYPHILIS CAUSING INTERNAL HYDROCEPHALUS AND SYMPTOMS OF CEREBELLAR TUMOR

REPORT OF A CASE WITH NECROPSY FINDINGS *

S. D. INGHAM, M.D.
Instructor in Neurology, Medico-Chirurgical College; Assistant Neurologist to the Philadelphia General and the Medico-Chirurgical Hospitals
PHILADELPHIA

The following case, studied in Dr. T. H. Weisenburg's wards of the Philadelphia General Hospital, is of considerable interest for several reasons. Although cerebral syphilis frequently causes symptoms of brain tumor, it generally does so by the formation of gummata in relation with the meninges or vessels, and not, as in this case, by occlusion of the foramen of Magendie and resulting chronic internal hydrocephalus. The comparatively frequent occurrence of congenital internal hydrocephalus in association with congenital syphilis has often been noted. The pathology of congenital hydrocephalus is not well established, but occlusion of the foramina of communication between the ventricular system and the subdural space of the brain has been found postmortem by various observers, and appears to be the cause of the condition in at least some of the cases.

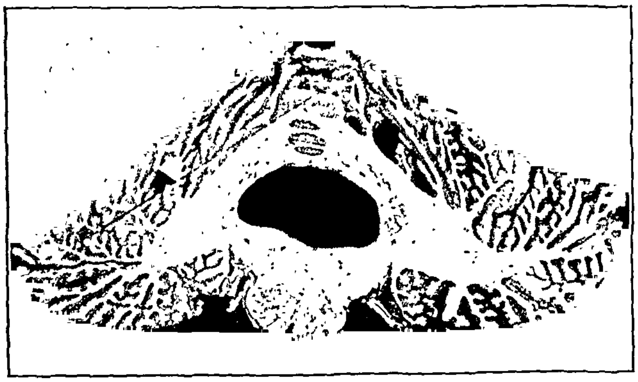

Fig. 1.—Stained section of the cerebellum and medulla showing the degree of the dilatation of the fourth ventricle, and the displacement and compression of the dentate nuclei.

Acquired, or secondary, hydrocephalus has been found in numerous cases to be due to mechanical obstruction of the foramen of Magendie or aqueduct of Sylvius by tumors, cysticerci, or as a result of tuberculous, suppurative or epidemic meningitis. Syphilitic meningitis, however, acting in this manner, seems to be a rare condition. Nonne ("Syphilis and Nervensystem") does not mention it, and in several text-books (Gowers, Oppenheim, Strümpell, Church and Peterson) consulted, syphilis was either entirely omitted or only vaguely suggested as a possible cause of acquired hydrocephalus.

The second point of particular interest in this case was the character of the cerebellar incoordination. During the period of his stay in the hospital (about four weeks), and no doubt for some time before his admission, the disequilibration became progressively worse, and from the first to the last was characterized by a constant tendency to fall directly backward, never to the right nor left. Physiologic experiments on animals (cited by Morat) teach us that destruction of the vermis, or bilateral destruction of the cerebellar hemispheres, will cause forcible extension of the head, opisthotonos, anteroposterior movements of oscillation, etc. Unilateral lesions of the cerebellum or its peduncles produce turning movements of various kinds and degrees, and in coordination on the same side of the body. Clinical experience confirms these experiments, but movements directly backward are very seldom observed, probably because central lesions of the vermis, and exactly symmetrical lesions of the cerebellar hemispheres, rarely occur. The incoordination in this case, together with other signs of intracranial neoplasm, led to a diagnosis of a tumor of the vermis.

History.—C. R., white, aged 42, was a salesman by occupation. Nothing of importance was elicited in the family history. He had a chancre at the age of 24, but gave no history suggestive of secondary or tertiary syphilis. He stated that he had not been well for two or three years, had had some difficulty in walking, pains from time to time in the arms and legs, headache rather frequently, and some difficulty with micturition, principally when beginning to urinate. His hearing had been somewhat impaired during the last year. His sister stated that he had been mentally dull for five or six years, and had had occasional attacks of nausea and vomiting, vertigo, and sometimes fainting.

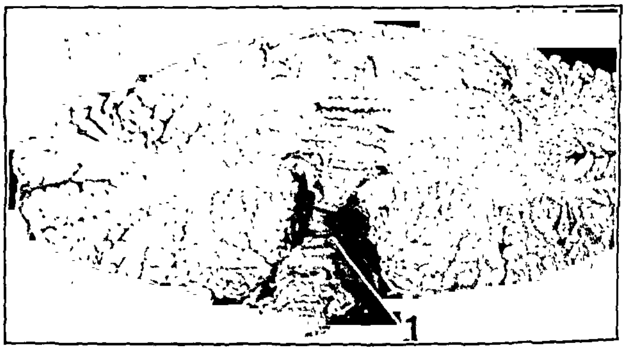

Fig. 2.—Part of the cerebellum removed showing site of the occluded foramen of Magendie (1) externally.

Examination.—He was able to walk at the time of his admission to the hospital, Aug. 30, 1908, when his condition was as follows: He was muscularly well-developed and nourished, and presented no gross motor paralysis, muscular atrophy nor cutaneous sensory loss. The pupils showed some inequality and irregularity of outline, but both reacted to light and to ocular movements. The fundi presented no pathologic changes, and there was no nystagmus. The actions of the motor cranial nerves were normal. In the upper extremities the muscular power was good, and there was no ataxia in the finger to nose test. All of the reflexes, however, were more prompt than normal. In the legs the power was also good, no ataxia was present (heel to knee test), the knee jerks were increased, especially the left, ankle clonus was present on both sides, and the Babinski sign was negative. The gait was slow but fairly steady, the steps short. He walked with the feet apart, head retracted, and after taking a few steps would come to a halt with a tendency to lean backward, sometimes taking a step or two backward to regain his balance. While standing with eyes open he exhibited a marked tendency to fall backward, and this was increased when the eyes were closed. The mental condition was poor; although he gave a fairly definite account of events in his past life, memory for recent events was very incomplete, and orientation for time was almost entirely lost.

Subsequent History.—From the time of his admission, until his death, four weeks later, he became gradually and progressively worse; mentally, more dull and finally stuporous; all of the reflexes became more prompt, with a tendency to spasticity on the left side. Slight ataxia developed in all of the limbs, and the loss of equilibration became so extreme that he could not remain in a sitting position, invariably falling backward, although the muscular power remained good. Incontinence of the sphincters appeared and persisted after about two weeks.

---

* From the Philadelphia Hospital and the Laboratory of Neuropathology of the Medico-Chirurgical College. Read before the Philadelphia Neurological Society, April 23, 1909.

Postmortem.—At necropsy the pathologic condition found was syphilitic cerebrospinal meningitis, which was especially marked at the base of the brain where the new tissue formation had caused thickening in the pia-arachnoid and complete occlusion of the foramen of Magendie. All of the ventricles of the brain were much dilated, but especially the fourth, where the distention had caused compression of the white matter of both cerebellar hemispheres, and displacement and compression of the dentate nuclei in a symmetrical manner. No gross lesions of any other character were present. That the foramen of Magendie was impervious was demonstrated by removing the pons, medulla and cerebellum from the cerebrum by an incision through the cerebral peduncles, and filling the fourth ventricle *via* the aqueduct of Sylvius with a solution of eosin; the specimen was then dissected and it was found that none of the stain had penetrated beyond the cavity of the ventricle. Microscopically, the usual changes of cerebrospinal syphilis were present in the meninges and blood vessels of the brain and cord, and in addition, degeneration of many of the cells in the dentate nuclei of both sides, and degeneration, even disappearance in places, of some of the cells of Purkinje in the cerebellar cortex. The distention of the fourth ventricle in this case evidently acted as a symmetrical bilateral lesion involving both dentate nuclei and vermis and accounts for the purely backward type of cerebellar incoordination.

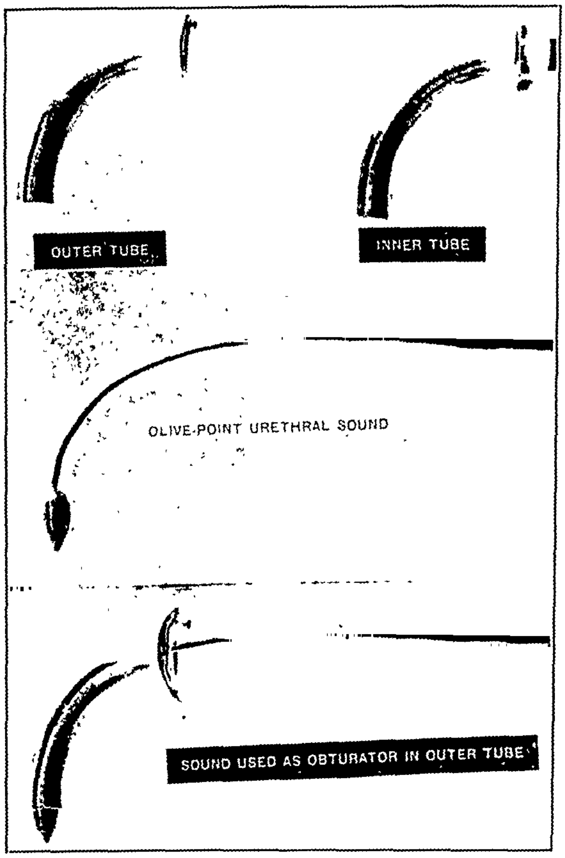
The Prevalence of Fleas on Rats and Squirrels.—Previous observations made under government auspices have shown the occurrence of plague in the ground squirrel. The conveyance of plague from rodent to rodent by means of the flea has been proved and it has been shown that the fleas that ordinarily infest rats and also those infesting squirrels will bite man. The possibility of the agency of the ground squirrel in spreading the plague to man is therefore shown. G. W. McCoy and M. B. Mitzmain, in *Public Health Reports*, July 16, 1909, give the results of further investigations in this direction. Rats and squirrels were combed to determine the varieties and average number of fleas which they harbor. While the large majority of fleas are found associated with their proper hosts, it was found that rat fleas occasionally infest squirrels, and vice versa. It has been shown that the rat will live in perfect harmony with squirrels in captivity. The average number of fleas found on a rat varied from 4.7 in one series to 7.6 in another. Live ground squirrels yielded a larger average, 34. Mice, rabbits, skunks and other similar animals were also found to be infested. The nests of rats were found to harbor more fleas than the animals themselves. By placing rats in cages with squirrels, and vice versa, it was shown that an interchange of fleas took place, indicating that fleas from rodents readily adapt themselves to hosts of different species.

OLIVE-POINT SOUND USED AS AN OBTURATOR

J. E. TUCKERMAN, M.D.
CLEVELAND, O.

Some four or five years ago, while his own physician was away, a man who had always worn a tracheotomy tube came to me to have the same replaced. The tube had been out some days and the opening was contracted from side to side. On trying to replace it, the tube acted much like a reamer or corer, and would not slip in without paring the edges of the opening. Resort to the makeshift shown in the illustration made the introduction easy. The matter passed entirely from mind until recently my brother, Dr. W. H. Tuckerman, had a like difficulty in introducing a tube, larger than the one being worn, into the trachea of a growing child who has constantly to wear a tube. Again the device shown made the procedure easy.



OUTER TUBE
INNER TUBE
OLIVE-POINT URETHRAL SOUND
SOUND USED AS OBTURATOR IN OUTER TUBE

An improvised obturator to facilitate introduction of tracheotomy tube.

An obturator might very well be a part of every tracheotomy tube. A tip could be made with a shoulder to fit the inner tube which could then act as an obturator during the introduction of the outer tube. Withdrawal of the inner tube and removal of the tip would then allow the inner tube, when replaced, to fulfill its usual office. No doubt the same or like makeshift has been used by others. Still, even though tracheotomy is not now the common operation it once was, the accompanying illustration may be of interest and perhaps will lead some instrument maker to design a complete tracheotomy tube.

BOWING OF THE SHAFT AS A CORRECTIVE MEASURE IN DEFORMITIES OF THE UPPER EXTREMITY OF THE FEMUR

EDWARD A. RICH, M.D.
TACOMA, WASH.

A class of deformity presents itself rather frequently to the orthopedist offering unusual difficulties on account of actual loss of bony tissue. Reference is made to those cases of absent epiphyses caused by acute suppurative arthritis, epiphysitis or tuberculous disease. The head of the femur is the common seat of such a lack. There presents, also, in the femur, abnormal deviations of the axis of the head and neck with the axis of the shaft, giving coxa valga, etc. For example, Figure 1 shows a defect in the femoral head due to arthritis; Figure 2 shows a typical case of coxa valga.

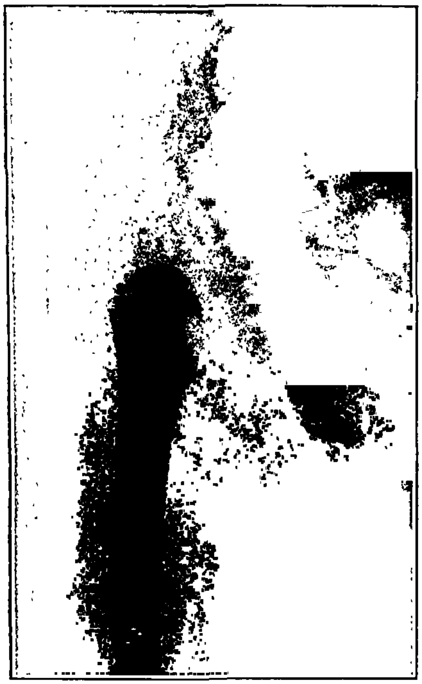

Fig. 1.—Femur, presenting deformity resulting from congenital arthritis (Case 1).

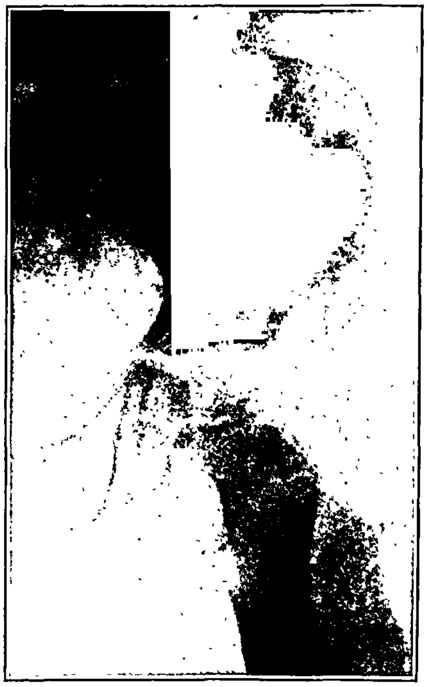

Fig. 2.—Case coxa valga; common type causing limp only (Case 2).

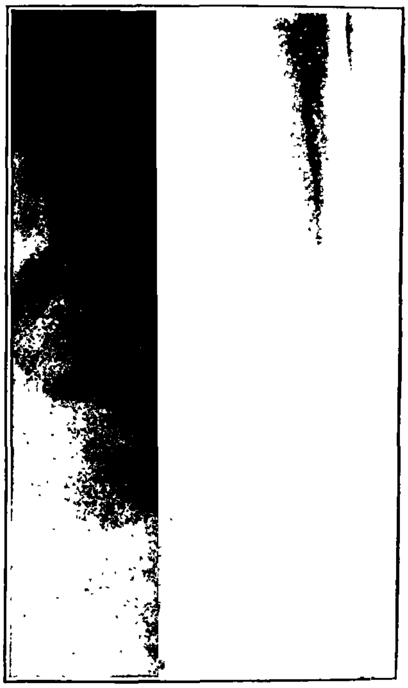

Fig. 3.—Result of femoral bowing in coxa valga (Case 3).

The question as to treatment has ever been a vexatious one, and authorities are apt to hedge. Lorenz advocates ankylosing the top of the femur to the acetabulum, but ankylosis is almost impossible in the very young. As a matter of fact, the results of these atypical cases have been far from satisfactory. Acknowledging that the idea was forced on me purely by an accident, let me report the results of a new mode of treatment, consisting in the bowing of the femur by artificial means so that it may maintain a position in the hip capable of performing function. Also let me report the results of the utilization of the same idea in other conditions at the femoral head. In coxa valga, bowing is used as a substitute for osteotomy.

A glance at the Figures 4 to 7 will show the purpose of the bowing. In weight-bearing the upward forces resolve themselves into the longitudinal and the lateral forces; the mean in any direction being the resultant. When by accident or deformity the direction of the resultant force falls in the lower half of the arc of the acetabulum we notice a tendency to dislocation, usually outward at first and then upward. When, however, the direction of the resultant pierces the upper half of the arc, as it does in the normal hip, this tendency to misplacement does not exist. Cuneiform osteotomies have endeavored to alter the direction of the resultant. For the same purpose I have bowed the femur. Of course, the method would be practicable only in childhood.

Case 1.—Girl, aged 3, presented to me in February, 1908, with history of an acute arthritis (suppurative) during first two months of infancy. Evidence of sinus in gluteal region and history of much discharge. Sinus closed end of second

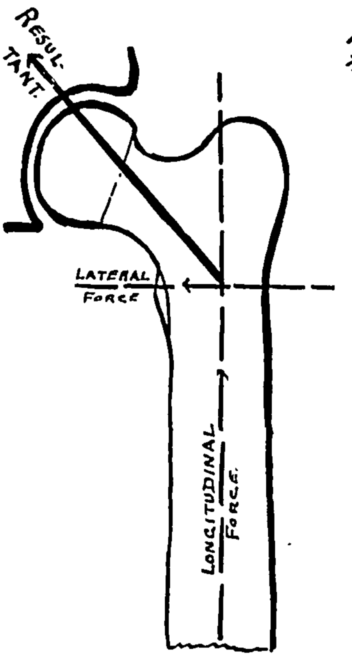

Fig. 4.—Diagram of normal hip, showing natural forces of weight-bearing and natural resultant.

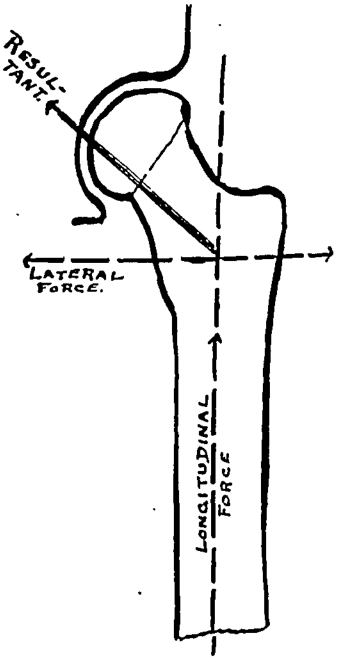

Fig. 5.—Diagram of hip in coxa valga, showing direction of resultant force with tendency increased to dislocation.

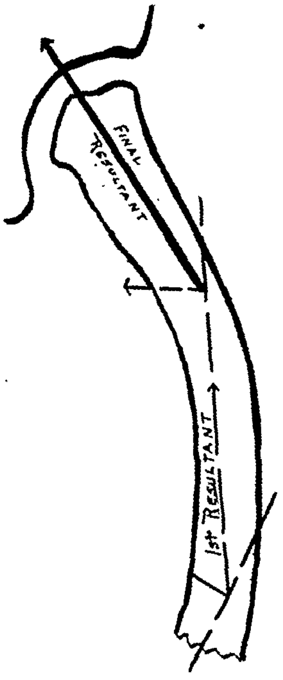
month. Only symptom noticed by parents was the limp that accompanied walking. The femur presented the appearance shown in Figure 1. The head was absent and dislocation was considerable.

When confronted with this condition in a child so young, I determined to reduce the dislocation and temporize by maintaining the thigh in extreme abduction, encasing in plaster as after the congenital hip replacements. This was done, the plaster including the knee, and the child returned home. An infectious disease in the home prevented her from returning to the city for three months. On her return I found, on the removal of the cast, that the child's rapid growth had bent the femur outward very markedly. My chagrin was lightened by the idea that such a bowing might be utilized to compensate for the lost angle at the femoral neck. Another cast was snugly applied and worn for two months. On the removal of this second cast I was delighted when the leg was adducted to note that considerable motion entirely failed to redislocate the hip. For the last six months or more I have retained the thigh in considerable abduction in a plaster spica and the knee straight but still maintaining the femoral bowing. I allow constant weight-bearing and have had no tendency to misplacement whatever.



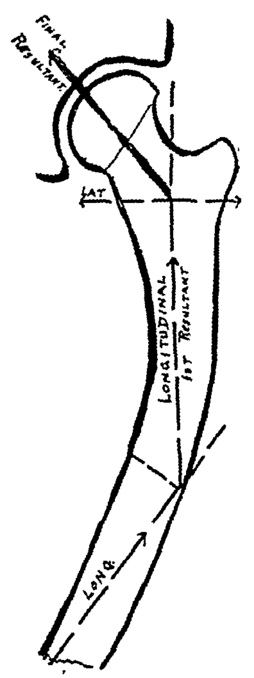


Fig. 6.—Diagram of hip in epiphysitis with loss of femoral head; femur bowed, showing final result of bowing.

Fig. 7.—Diagram of hip in coxa valga with bowed femur, showing forces of weight-bearing modified by bowing of shaft, with direction of consequent resultant.

CASE 2.—Girl, aged 4; history unimportant except that right-sided limp had been present on weight-bearing since child learned to walk. No pain or other symptoms whatever. Radiograph (Fig. 2) shows coxa valga deformity with angle of 165 degrees. Cuneiform osteotomy was refused. Rather than resort to fixation in abduction I decided to try bowing of the femur. In four months I had produced an artificial bowing outward by applying a tight-fitting round-and-round plaster, the thigh flexed and abducted to right angles with the body. When sufficient bow was produced the patient was freed of splints and under observation weight-bearing was allowed. There is no shortening. The limp disappeared and walking is normal.

CASE 3.—The essential points in the history of this case of coxa valga are illustrated in the history of Case 2. Figure 3 shows the result.

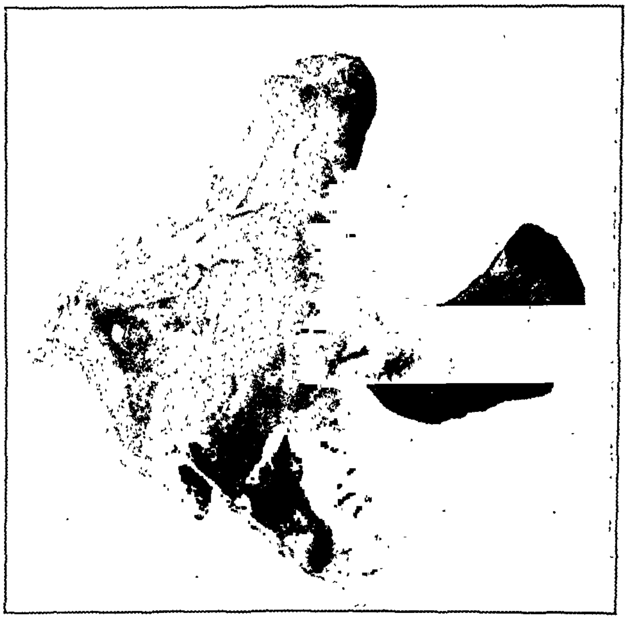
Provident Building.

SHOT IN THE APPENDIX VERMIFORMIS *

H. S. MARTLAND, M.D.
NEWARK, N. J.

History.—J. D., male, aged 30, was admitted to the surgical division of the City Hospital, service of Dr. E. R. Haussling, suffering from an acute appendicitis, which he had had for two days. The patient was immediately operated on, and the appendix, which had not ruptured, was removed. A localized abscess developed, which drained well. The patient left the hospital in twenty days cured.

Appendix.—The appendix measureed 5 cm. in length; its outer two-thirds was triangular in shape, and sacculated. (See illustration.) The dilated portion contained pus, necrotic tissue, fecal matter, and twenty-two shot. The size of the shot was No. 8, and they showed signs of discharge. Microscopic examination showed an acute suppurative inflammation, together with a chronic process. The proximal end presented a thickened and rigid muscularis, which caused the lumen to remain patent and large.



Appendix, showing the presence of shot.

It seems probable that the presence of the shot had only an indirect part in causing the present attack, and that their presence in the appendix was due to the unusually large and rigid opening into the cecum, caused by a previously existing inflammation.

The patient attributes the presence of the shot to the eating of stewed rabbit.

Howard Kelly says:

> Of the heavy bodies which gain access to the appendix, the most common are shot or bullets. The rôle of shot resembles that of concretions, being purely passive; such bodies may occasionally produce abrasions of the mucous membrane, but, as a rule, they act indirectly, by obstructing the lumen, or by causing pressure anemia of the wall, and diminishing the vitality of the tissue.

Foreign bodies in the appendix, however, are unusual; in 1,000 cases at the Johns Hopkins Hospital they occurred in four cases only.

Physical Education.—The attempt of the National Education Association to persuade congress to organize a bureau of physical education similar to those found in most of the progressive countries of the world should be aided by all good citizens.—P. C. Phillips, in *Hygiene and Physical Education.*

PRACTICAL WINDOW VENTILATION

WILLIAM J. MANNING, M.D.
Medical and Sanitary Officer, Government Printing Office
WASHINGTON, D. C.

One of the most difficult tasks, where many persons are gathered together under one roof, during the winter season and inclement weather, is the proper enforcement of healthful ventilation and the regulation of temperature in work rooms without meeting many protests.

Tersely stated, the idiosyncrasies of James Brown do not coincide with the idiosyncrasies of John Smith, so that what blows hot for John blows cold for James, and as a result one desires the window tightly closed, no matter the degree of temperature, and the other demands the window open.

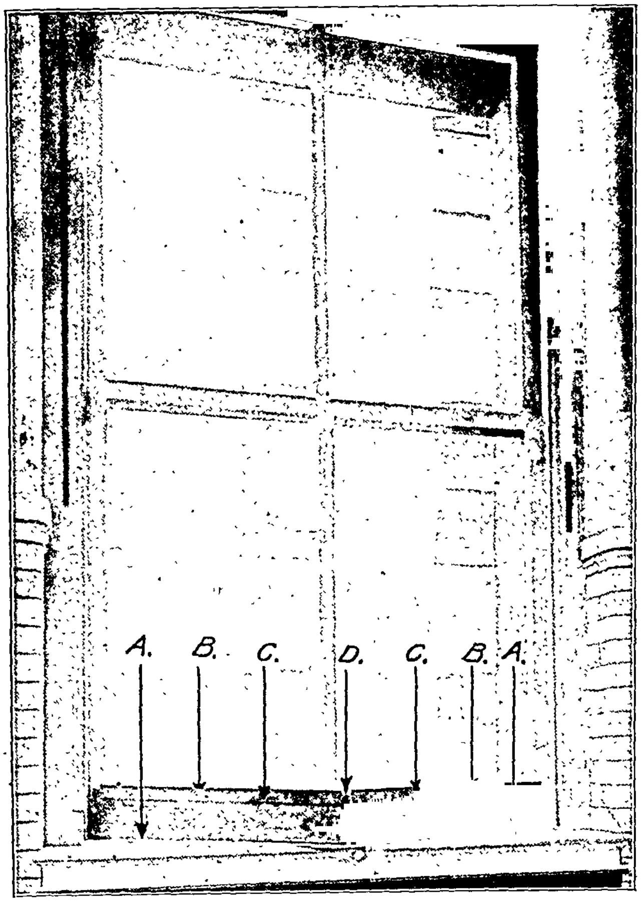

Fig. 1.—Ventilator about to be placed in position under window-sash.

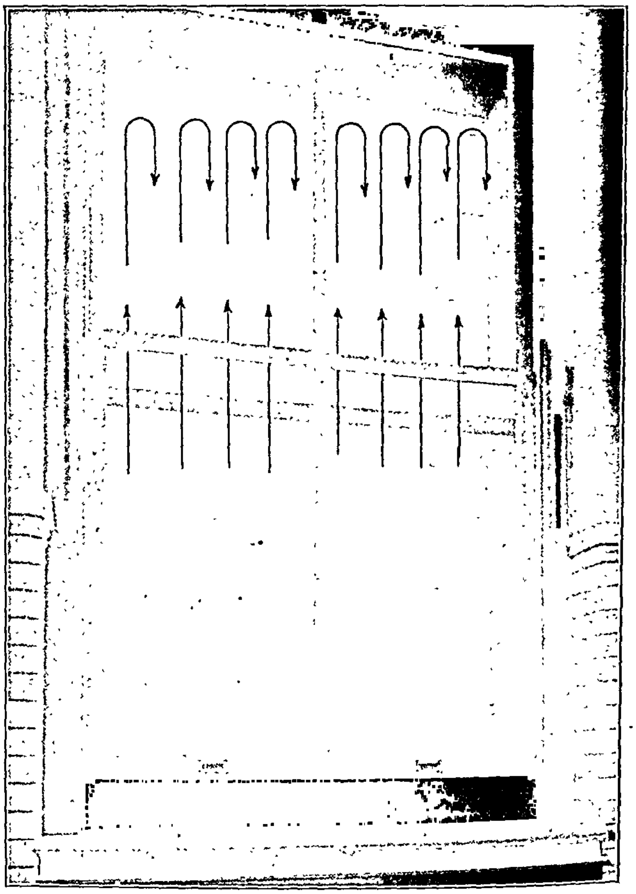

Fig. 2.—Ventilator in place with window closed, the air passing upward between top and lower window-sashes.

Of course, in many of the larger buildings over the country, systems of internal ventilation are in use, some effective and some ineffective, but all very expensive and complicated. It is the smaller buildings, however, that interest me.

To aid the ventilation of those buildings which are not thus provided for, such as small workshops, factories, stores, etc., and to aid, even where ventilation systems are in use, has been my idea in publishing the present modification of a very old method of placing a board lengthwise under a window.[1]

It will be noticed on reference to Figure 2 that a current of fresh air is constantly entering the room far above the heads of those persons who may be employed within such apartment and in such a manner that no person is directly exposed to any draft or to "catching cold." One such ventilator in every third window in a large room will be found sufficient, in the majority of cases, to admit sufficient air to keep otherwise closed rooms in a healthful condition.

I have found this simple method, as constructed and in use in this office, to be most practical, cheap and effective. Any "handy man" about a factory or workshop with a saw, hammer, plane, a few nails, hinge and a piece of board may construct one of these ventilators at the cost of a few cents by following the directions given.

Measure the distance between window-frame from side to side, or flush with ends of window-sash that works up and down in the groove, or between the parting strip and window-frame; now select two boards not less than six inches in height and each half the length measured, and of the same thickness as the window-sash, or made so by piece of wood or cleats nailed to the ends of the boards making up for such thickness; bevel the under edges of the boards (AA, Fig. 1) to fit the window-sill; bevel the top edges of the boards (BB, Fig. 1) to fit the descending window-sash. Nail a piece of wooden moulding or a common lath (CC, Fig. 1) to the inner top of the edge of the board, within which the closed window-sash will rest as shown in Figure 2.

This joint (CC, Fig. 1) may be lined with felt, or tailors' woolen selvage edges that permit the window-sash to jam tightly into the joint, making it air-tight, if desired, and preventing direct draft on any person, no matter how cold it is or how high the wind is blowing.

---

[1] Egbert: Hygiene and Sanitation.

A hinge, bending outward, is now placed at the point marked (D, Fig. 1). When putting the ventilator in position, pressure outward simply snapping it in place, ready for descent of window-sash; pressure inward "breaks" the board for removal.

Large thermometers, about two feet in length, are suspended from the ceilings of work-rooms during the winter season. The figures 70 and 80 on the scale, marking the extremes of healthful indoor temperatures during the season mentioned, have been enlarged to one inch in size, and are further distinguished by broad red arrows placed above and below the figures respectively. The scale is, therefore, readable from all parts of the room, and serves as a constant indicator or danger signal in a silent, effective manner.

Therapeutics

DIABETES

As is true of all diseases, this could be more successfully treated if we knew in each instance its exact etiology. It is not necessary to rediscuss the known disturbances that cause glycosuria, but Dr. Alfred King, of Portland, Me. (*New York Medical Journal*, July 3, 1909), terms this disease infectious, and states his excuse for such a classification to be the fact that he has found, in sixteeen patients suffering with this disease, the yeast fungus (*Saccharomyces cerevisiæ*) in the blood. He takes a drop of blood from a finger which has been made sterile, and not only finds the yeast fungus under the microscope, but has been able to grow the fungus in culture fluids. His method may be learned from his article. He has also found by a study of the opsonic indices that when the patient is doing well his opsonic index is high; when the patient is debilitated, miserable, and losing ground, his opsonic index is low. He has also found that hypodermatic injections at intervals of from three days to a week of from 5 to 15 minims of the fluid produced by a twelve-hour growth of the fungus (of the strength of 100,000,000 of dead fungi in 15 minims of sterile salt solution) have raised the opsonic index and improved the condition of six patients.

King allows some starchy foods, as a little oatmeal, half a slice of bread, or a small potato, with each meal.

From his investigations King says: "Because diabetes is a disease of fermentation; because the yeast fungus is often found in the blood; because its actions explain all the symptoms as well as the pathologic conditions; because the patients show a disturbed power of resistance to this fungus; and because this lowered resistance is increased by treatment with vaccine, I believe this yeast fungus is the cause of diabetes, and that it should be treated as an infectious disease." He thinks this fungus may be removed by the use of antiseptics, but he has not yet learned how to do this.

His general treatment by diet, for the amelioration of symptoms, and the condition of acidosis are the same as are so well understood.

This interesting discovery by King should stimulate physiologists to a general study of the frequency and constancy of the yeast fungus in the blood of diabetics.

INTESTINAL OBSTRUCTION

It is not the purpose of this article to discuss all of the forms of obstruction that can occur in the intestine, but to offer a caution or two for the necessity of early diagnosis and immediate surgical consultation and early operation in all forms of absolute obstipation.

If obstruction is diagnosed or even suspected, cathartics must ordinarily not be administered. Also morphin, by masking the symptoms, is almost dangerous. As well pointed out by Dr. H. F. Waterhouse (*British Medical Journal*, May 29, 1909), the obscuration of the condition by one good dose of morphin may postpone a necessary operation until gangrene, septic exudate, or perforation and consequent peritonitis has made the prognosis fatal, and a favorable result from operation almost impossible.

While pain in the abdomen may be referred to any part, the diagnosis of localization is made by the region of tenderness, and the ability to find tender points and localized lesions becomes more and more difficult the later in the condition the attempt is made. In other words, very careful abdominal examination should be made whenever there is abdominal pain. Later, tenderness may be so generalized as to make a localization impossible.

The object of Waterhouse's paper is to show that in his experience volvulus, twisting of the intestine, is more frequent than has been supposed, and probably in many cases cured spontaneously. He finds that an elongated lower segment of the sigmoid part of the intestine is the most frequent position of such twisting. Prolonged constipation, and this in older and debilitated patients especially, elongates the lower part of the sigmoid of the intestine and the upper part of the rectum (this region being termed the omega loop), gives the excuse for this region being the region of most frequent twisting. Early examination of the abdomen will generally show that this is the part of the intestine in trouble. Pain, obstipation, and gas distension are the immediate symptoms. Vomiting, Waterhouse points out, may not be present in volvulus of this region.

High enemas of warm water, with the patient in the knee-chest position, will sometimes untwist this part of the intestine, and the symptoms may cease as quickly as they began. During the time of doubt and waiting before an operation is deemed advisable, all food should be absolutely withheld, although the patient may be allowed water by the stomach.

Waterhouse finds that the onset of gangrene of the twisted bowel is indicated "by the pulse becoming rapidly weak and quick, and by the septic appearance of the patient."

It must be emphasized that ordinarily to be successful operation must be done before such symptoms are in evidence.

Massage Best Remedy for Loss of Hair.—Ingenious men, says Dr. T. O. Cobb, in *New York Medical Journal*, are continually contriving new kinds of shoes, new suspenders, and hundreds of different kinds of braces, but so far no one has taken up the idea of making a hat which will hold on the head and not blow off, and at the same time not bind the head all around like a constricting band. Some one ought to invent a hat which will prevent baldness. Hundreds of remedies are on the market which are advertised as sure hair restoratives, but not one of them will bring back one hair once the hair follicle is atrophied and functionless; nor will any of these remedies prevent the falling of hair unless the habits of the sufferers are changed. At best these remedies are merely skin irritants, which promote a slightly increased flow of blood to the scalp. Dandruff cures are mostly fakes. The only good accomplished by these medications is the scalp massage indulged in while applying them, and the practitioner should make a fight against their use.

SATURDAY, OCTOBER 16, 1909

THE PATHOGENESIS OF TYPHOID FEVER

The typhoid bacillus is one of that troublesome group of organisms which produce their effects through poisons which are liberated only when the bacteria are disintegrated—troublesome because the animal body seems to have little or no power to produce antitoxins for these "endotoxins." Hence the reason for the early abandonment of the once-cherished hope of universal antitoxin therapy for all infectious diseases. It also happens that the chief means of defense against the typhoid bacilli consists in the power of the blood serum to cause bacteriolysis, and as by this bacteriolysis the endotoxins are liberated but not neutralized, it results that the destruction of large numbers of typhoid bacilli in the blood may not always be an unmixed blessing. To illustrate by an experiment, if a large dose of typhoid bacilli be injected into an animal that has been immunized to this organism, and into another, nonimmunized, animal an equally large dose be injected, it may happen that the immune animal will die in a few hours while the normal control may live much longer. The reason for this is that the immune animal has acquired the power of destroying typhoid bacilli, and by producing the rapid disintegration of the injected organisms it causes their endotoxins to be liberated in a single large dose, against which the animal has no defense. Such an animal may die from the bacterial intoxication when cultures show that the blood is entirely free from living bacilli, while, at the same time, the control may live much longer with abundant living bacilli in its blood.

As in typhoid fever the bacilli are present in the blood almost constantly and continuously from the earliest stages, it is evident that this matter of the liberation of endotoxins by bacteria destroyed within the blood must be of much importance in the clinical manifestations of the disease. That the typhoid bacillus may be present in the body and not cause typhoid fever is well known, especially since the prevalence of bacillus-carriers has become recognized. It may even invade the tissues and cause extensive lesions, such as post-typhoid bone abscess, cholecystitis and pyelitis, without producing the features of typhoid fever. Therefore, it would seem that to produce typhoid fever the bacilli must grow in a situation where they have free access to the blood; entering the blood they cause the clinical condition of typhoid fever by becoming disintegrated and liberating their endotoxins.

From their studies of the bacteriology of the blood in typhoid, and experimental investigations on animals, Coleman and Buxton[1] have developed an interesting and plausible theory of the pathogenesis of the disease. They believe that the atrium of the infection is in the lymphatic structure of the intestinal wall; from here the bacilli reach the general lymphatic system and the spleen, where they seem able to grow, being here in a measure protected from the bactericidal power of the blood. After they have grown to a sufficient amount, corresponding to the period of incubation, they overflow into the blood, where, the bacilli undergoing bacteriolysis, the endotoxins are set free and cause the symptoms of the disease. It seems probable that in most cases of typhoid the bacilli do not multiply to any considerable extent in the blood stream, but are destroyed there; hence typhoid fever is not to be looked on as a septicemia, but a bacteriemia. When the endotoxins are liberated in the tissues, as in post-typhoidal suppurations, we do not get the typical symptomatology and pathology of typhoid; these result only from destruction of numerous bacilli in the blood stream.

Subsidence of the fever seems to depend on the cessation of discharge of bacilli from the lymph glands into the blood, probably because the immunity processes have succeeded in checking the multiplication of the bacilli in the lymphatic tissues. It is possible that those cases in which an intermittent temperature persists after the original febrile movement has subsided may be due to irregular discharge of bacilli from some lymphatic organ in which the bacilli still continue to grow. Relapses probably arise in this way, for it is known that the spleen sometimes remains large after subsidence of fever in patients who subsequently relapse, and it may well be that this enlargement indicates the local persistence of the infection, which may later flare up as the immunity reactions wane. That the resistance to the typhoid bacillus does wane, especially as regards local rather than systemic resistance, is shown by the frequency with which after recovery from systemic infection local infections appear in the form of abscesses, cholecystitis, etc.

This hypothesis not only has good experimental support, but it also is more easily accepted than the view which seemed to be becoming prevalent that typhoid fever is in reality a septicemia, for this latter view requires the assumption that the bacilli are multiplying in blood which, experiment shows, is strongly bactericidal. As support by analogy, Coleman and Buxton refer to the case of the related organism, *Bacillus paratyphosus*, which when infecting the intestines produces merely the clinical picture of a gastroenteritis, but when it has invaded the lymph glands and blood produces a disease clinically indistinguishable from typhoid fever.

---

[1] Am. Jour. Med. Sc., 1907, cxxxiii, 896; Jour. Med. Research, 1909, xxi, 83.

The power of typhoid bacilli to persist in the lymphadenoid tissues long after they have disappeared from other organs may be considered to be another of the many examples of specific adaptation of bacteria to a special soil, a property of bacteria which was first made prominent by Welch.

THE PURIFICATION OF WATER WITH BLEACHING-POWDER

We have recently referred[1] to the use of ozone for the purification of drinking-water and have dwelt on the fact that the high or indeterminate cost of the various ozonization processes stands to some extent as a barrier to the general introduction of this method. It might be added further that ozone is not the only substance that can be employed for the "practical sterilization" of water, and that, from a chemical point of view other substances are theoretically available for the treatment of large public supplies. Experiments lately conducted on the Jersey City water-supply appear to bear out this view.[2] Commercial bleaching-powder, an impure product the active ingredient of which is hypochlorite of calcium, has been used increasingly in the disinfection of sewage effluents during the last few years, and on at least one occasion (Maidstone, England, 1897) it has been used to disinfect a public water-supply suspected of carrying the infection of typhoid fever. Its use on a large scale in the Jersey City experiments is therefore only a further utilization of its already well-known germicidal powers. When calcium hypochlorite is added to a natural water, hydrogen oxychlorid or hypochlorous acid is released in the water. This compound is a very weak acid, but an extremely powerful oxidizing agent. The treatment is, therefore, in no sense a chlorin treatment, but purely one of oxidation quite comparable in this respect to the process of ozonization.

The bleaching-powder employed in the Jersey City experiments contained on the average about thirty-five per cent. of "available chlorin," equivalent to about seven and nine-tenths per cent. of "available oxygen." The powder was applied during the latter part of the experiments in the proportion of about five pounds per million gallons of the water treated. The bacterial results were very favorable, the total number of bacteria in the treated water averaging only fifteen and *Bacillus coli* being isolated only once out of 455 samples examined. The process has one important chemical advantage, namely, that it brings about a reduction in the amount of carbonic acid in the water (through action of the calcium) and hence lessens the incrusting and corrosive action on iron and steel pipe.

The total cost of the process is stated to be between twenty and twenty-five cents per million gallons, or only about one-twentieth the cost of the ozonization process, so far as the latter can be determined from available data. When water-power can be obtained without additional expense, available chlorin can be produced in the electrolytic cell and the whole process thereby considerably cheapened. It should be said that the water dealt with in the Jersey City experiments does not appear from the published analysis to be very highly polluted, the bacterial content of the raw water ranging as low as 30 per c.c. and rarely going above 1500. There seems indeed to be some question as to the necessity for disinfecting this particular water, and the matter is still before the courts. Further experiments under different conditions should throw more light on the real efficiency of bleaching-powder as an agent for the purification of water-supplies, and we shall probably not have to wait long before these are made.

DISSECTION THEN, VIVISECTION NOW

In the midst of the attention attracted by the recent meeting of the antivivisectionists in London we were reminded of a corresponding agitation against dissection at the beginning of the nineteenth century. Bodies were extremely difficult to obtain, and they were secured by all sorts of underhand and illegal means. A whole series of murders committed for the sole purpose of obtaining bodies to be sold to medical schools had been unearthed in England and Scotland, yet the opponents of dissection absolutely refused to listen to reason and allow the passage of an anatomy bill by which the bodies of the poor who died in charitable institutions were to be given to medical schools for dissection purposes. The bill met great opposition in parliament from men who sentimentally insisted that such a law would work great harm to the poor. In the course of the debate Lord Macaulay, better known for his essays than his speeches, delivered a short address on Mr. Warburton's anatomy bill which Mr. Hunt had attacked with great asperity. Because his speech contains the answer to some of the sentimental objections of the "antis" in our day and, above all, because it illustrates the fact that no great humanitarian movement ever makes its way without serious opposition on the part of people who think themselves humanitarians, we quote two of the passages:

"If we could do all that, in the opinion of the member for Preston, ought to be done, if we could prevent disinterment, if we could prevent dissection, if we could destroy the English school of anatomy, if we could force every student of medical science to go to the expense of a foreign education, on whom would the bad consequences fall? On the rich? Not at all. So long as there is in France, in Italy, in Germany, a single surgeon of eminent skill, a single surgeon who is, to use the phrase of the member for Preston, addicted to dissection, the surgeon will be in attendance whenever an English nobleman is to be cut for the stone. The higher orders in England will always be able to produce the best medical assistance. Who suffers by the bad state of the Russian school of surgery? The Emperor Nicholas? By no means. The whole evil falls on the peasantry. If the education of a surgeon should become very expensive, if the fees of surgeons should consequently rise, if the supply of regular surgeons should diminish, the sufferers would be not the rich, but the poor in our country villages, who would again be left to mountebanks, and barbers, and old women, and charms, and quack medicines. The honorable gentleman talks of sacrificing the interests of humanity to the interests of science, as if this were a question about the squaring of the circle or the transit of Venus. This is not a mere question of science; it is not the unprofitable exercise of an ingenious mind; it is a question between health and sickness, between ease and torment, between life and death. Does the honorable gentleman know from what cruel suffering the improvement of surgical science has rescued our species?"

---

[1] THE JOURNAL, Aug. 21, 1909, liii, 636.
[2] Engin. News, June 24, 1909.

We feel sure that what Lord Macaulay said at the end of his speech with regard to dissection he would, if called on, repeat at the end of a corresponding speech in a vivisection discussion before the House of Commons at the present time. What he has to say, therefore, is of interest, especially because the two situations so nearly resemble each other:

"I think this is a bill which tends to the good of the people, and which tends especially to the good of the poor. Therefore, I support it. If it is unpopular, I am sorry for it. But I shall cheerfully take my share of its unpopularity. For such, I am convinced, ought to be the conduct of one whose object it is not to flatter the people, but to serve them."

SCORPION VENOM AND ANTIVENOM

The sting of such scorpions as are encountered in this country seems not to be usually serious, although extremely painful and sometimes followed by dangerous sloughing and infection. In Egypt, however, scorpions are encountered which cause no inconsiderable fatality in children under 12, though the sting is rarely fatal in adults. The reason for this limitation of fatalities to children has been shown by Wilson, of the Egyptian Government School of Medicine, to depend on the fact that the average amount of poison in the most venomous of the Egyptian scorpions is capable of killing but about thirty-five kilos. During seven years there were recorded 153 deaths from scorpion sting in Cairo, while the incidence of deaths from this cause is, naturally, much higher in the country districts. In Assouan scorpions caused 1.6 per cent. of the total death rate, according to government statistics.

Although the poison from the scorpion resembles in some respects the snake venoms, yet it differs in many important particulars, especially in that it is not hemolytic, and the symptoms in animals, as described by Wilson, resemble much more closely the symptoms observed in animals dying from anaphylactic intoxication with proteins than they resemble snake poisoning. Different species of animals vary greatly in respect to their susceptibility to scorpion poison, although nearly all animals are seriously poisoned by the venom of a single sting. An interesting exception was found by Wilson to exist in certain desert animals of Egypt, which live under conditions which bring them into frequent contact with scorpions. Such animals, including desert rats, hedgehogs and foxes, possess a high degree of immunity, and a native house mouse was found also to be immune, although the ordinary mice and rats are very susceptible. It is also reported that some people who live where scorpions abound are immune to their stings, and some of these persons claim to make themselves immune to the scorpion by repeated small doses of the poison administered by pricking the skin with the stings removed from scorpions. Todd takes pains to state, however, that the Arabs who exhibit scorpions in the streets of Cairo for the entertainment of tourists are not immunes, but protect themselves by cutting the points off the stings of the scorpions. The old tradition that when a scorpion is surrounded by a ring of fire it commits suicide with its own stings is entirely fabulous, for the scorpion, like other venomous creatures, is immune to its own poison; indeed the blood of the scorpion was found by Metchnikoff to have considerable antitoxic power against scorpion venom.

The mortality, not to mention the serious effects produced by non-fatal stings, from scorpions in Egypt is sufficient to make the preparation of an antitoxin desirable, and this task has been accomplished by Dr. Charles Todd,[1] of the public health department of the Egyptian government. Calmette asserts that his antiserum for cobra venom neutralizes the venom of certain scorpions, but Todd found it ineffective against the venom of the scorpions of upper Egypt. Antiserum prepared by immunizing horses with scorpion poison, however, was capable of neutralizing in 2 c.c. doses the poison of one scorpion, and had both prophylactic and curative properties. During last summer this serum was in use in Egypt, and the results, both as to mortality and reduction of pain, are said to have been favorable.

INSTITUTIONAL CARE OF THE TUBERCULOUS

The tuberculosis campaign has passed through several distinct stages, and with increasing experience new points of view demand a change of tactics. At one time the prohibition of the use of milk and meat from tuberculous cows assumed the prominent rôle. Again, the sanatorium has been expected to solve the problem by education and cure of patients in the early stages. This method has been successful only in a degree, new cases continually developing. The source of contagion in these new cases is generally to be found in the homes of patients in the advanced stages, whom it has not been thought worth while to admit to sanatoriums. To remove this source of the disease the visiting nurses' movement was instituted, whose aim was so to educate and to care for the advanced consumptive that he might no longer be a menace to his family and neighbors. Mary E. Lent,[1] head nurse of the Instructive Visiting Nurse Association of Baltimore, reviews the work of her association, and concludes that, while good has been done to individuals, the method, as a means of preventing the spread of tuberculosis, is a failure. She says: "As a matter of fact, the experience of four years of continuous work in the homes of tuberculous patients of the class under consideration has demonstrated to me that the results hoped for have not been obtained and, moreover, are not obtainable by this method." The principal reason for this failure is the poverty of the people, who are unable, for lack of means, of time and of proper surroundings, to give themselves or their friends proper care. Advanced patients lack the moral stamina to carry out strictly the hygienic instructions of the nurse. There is a great difference between the care which can be exercised even by a conscientious patient and the scientific application of the rules for prevention in a well-appointed hospital.

---

[1] Jour. Hyg., 1909, ix, 69.

Segregation or isolation is the logical solution of the problem thus presented; but it must be borne in mind that we are dealing with independent citizens on whom the attempt to force segregation or isolation may react very unfavorably. In Germany great difficulty has been experienced in getting patients to go to hospitals for advanced cases on account of the feeling of the patients that the hospital is merely a place in which to die. The very terms "segregation" and "isolation" are objectionable, and our contemporary suggests that the term "institutional care" be used instead.

In removing the prejudices of the people and preparing patients for institutional care, the services of the visiting nurse are indispensable. While she cannot train patients to prevent the spread of the disease, amid the surroundings of poverty, she can by her investigations impress on the community the need of institutional care in these cases, and she can lead the patients themselves to see how much better it would be, both for themselves and for their family and friends, if they would accept the proffered institutional care. This much has been accomplished by the work in Baltimore, it seems, for it is stated that the patients there do not shun the hospital as patients do in Germany.

Whether institutional care will furnish a complete answer to the tuberculosis problem may well be doubted; but it has its important place in the agencies for controlling the disease, which has its roots deep in the social conditions which make for poverty, physical and moral degeneration. To remedy these conditions may be the task of more than one generation, but the urgent demand appears to be to extend the work of the visiting nurse and to supplement it by providing institutional care for such patients as she can induce to accept it.

THE SUSCEPTIBILITY OF RODENTS TO PLAGUE

It would be reasonable to expect that in communities where plague had long existed among rodents some would recover and in future be immune to the disease, and this has been shown to be the case with rats in India.[1] It is rather surprising, however, to learn that a large percentage of the rats (*Mus norvegicus*) in San Francisco are refractory to plague infection even when submitted to the rigorous test of inoculation with highly virulent cultures of the plague bacillus. McCoy,[2] of the Public Health and Marine-Hospital Service, during his investigations of plague in the federal laboratory at San Francisco, has found that from 20 to 70 per cent. of the large (old) rats experimented on were partially or entirely immune to laboratory infection. The percentage of immunity was found, however, to be not nearly so high among the smaller (young) ones. The arguments advanced to show that this immunity is natural and not acquired by reason of a previous attack of the disease are based on the high percentage of the immunity compared with the low percentage of rat plague in San Francisco, and the fact that some of the immune animals had been born after the subsidence of the plague. The question arises as to whether immunity to plague may be hereditary, as has been shown by Anderson[3] to be the case with immunity to diphtheria toxin. Experiments[4] made by McCoy with other rodents gave interesting results. He shows that field mice (*Microtus californicus*) are moderately susceptible to the disease and that gophers (*Thomomys bottæ*) are highly refractory to the infection. The most important fact brought out was that ground squirrels (*Citellus beecheyi*) seem to have no appreciable degree of resistance to the disease, as nineteen of these rodents were inoculated and all died of acute plague. This fact may be of some significance in connection with measures for the extermination of these rodents in California, where, according to reports, plague-infected squirrels are being found in considerable numbers. Laboratory experiments must, of course, be interpreted with considerable reservation, but those referred to would seem to indicate that there is small probability of the infection dying out spontaneously among these animals.

PHYSICIANS AND RAILROAD COURTESIES

It probably happens practically every day in the year that some physician somewhere in the United States is on a railroad train when an accident happens, and naturally offers to do whatever he can for the injured. Often it is imperative that such immediate service should be rendered to save a life in imminent danger, or to protect the sufferer from the hazards of bungling, inexpert interference. It is reasonably sure that a certain number of lives are saved by such unsolicited medical aid every year; and it is beyond all doubt that many persons injured in railway accidents are spared long convalescence, because through prompt medical aid they escaped the danger of meddlesome interference

[4] Jour. Infect. Dis., vi, No. 3, 283.

with their wounds at the beginning. In a certain number of these cases the injured persons are able and willing to pay for the physician's services; but such cases are extremely few. The services are rendered in any case; and the presence of the physician, especially if the injured persons are taken aboard the train to be carried to a more or less distant hospital, is a great saving of worry for patients, their friends and fellow-passengers and the employees of the railroad. But should this work be gratuitous? When the injured person himself is unable to pay, it would seem to be proper for the railroad company to make some compensation to the physician, even though his services may have been spontaneously offered. The railroad company is not a subject of charity. It is, as a rule, responsible for the accident; by prompt medical services it is frequently saved no inconsiderable sum in damages, because the patient recovers sooner and the consequences of his injury are not so serious. The present custom, however, is to allow no compensation to the physician and to consider that he has simply performed one of the acts of charity which are so common in his professional work. This policy is a relic of the old days when it was the custom for railroads to get as much out of the community as they could and to return just as little as possible. The modern railroad, however, is run on a much more liberal basis. There is a definite realization that duties are owed to all those with whom the railroad is brought in intimate relations. Apparently the physician is the only one who has not yet come within the purview of this new policy. Possibly it is the physician's own fault; possibly, if the profession would call the attention of railroad officials to the injustice of the present conditions, they would be remedied. Certain it is that every physician who gives of his time to the care of an injured passenger traveling with him should receive due compensation for what he does; and the railroad should not shirk its obligations in this matter.

Pancreatic Secretion.—P. T. Herring and Sutherland Simpson (*Quart. Jour. of Exper. Physiol.*, 1909, ii, 99), studied the pressure of the pancreatic juice in the pancreatic ducts of cats and dogs. In this connection the fate of the pancreatic secretion after the ligation of the duct was also investigated. It was found, as was shown by Langendorff, that the blood contains among other things, a larger amount of diastatic ferment after ligation of the duct. The proteolytic ferments of the blood were not increased. It then seems evident that the pancreatic juice, after the ligation of the duct, is thrown into the circulation. The proteolytic ferment does not make itself apparent in the blood, since the trypsinogen has no chance to be activated by the intestinal juice. "If the obstruction of the pancreatic secretion is a permanent one, the continual escape of pancreatic juice may be an important factor in the production of the fibrosis which follows ligature of the duct. This, indeed, is the explanation given by S. Pawlow of the ultimate changes which result from such a procedure. Atrophy of the gland substance itself may quite well be secondary to the outgrowth of connective tissue, and comparable to the atrophy of the parenchyma which occurs in cirrhosis of the liver." When the pancreatic duct or ducts are obstructed the pressure of pancreatic secretion rises to a height near to that reached by the bile in obstruction of the common bile duct. The intravenous injection of duodenal extract brings about a rapid rise of pressure in the pancreas after ligation of the duct.

Medical News

GEORGIA

Free Pasteur Treatment.—The Georgia State Board of Health reports that the free Pasteur treatment, which has been established in the state for the past year, has been employed in the case of 572 persons bitten by rabid animals, and that only one death has occurred.

Colleges Open.—Hospital Medical College, Atlanta, opened for its second annual term, September 21.——The fifty-fifth annual session of the Atlanta College of Physicians and Surgeons opened September 22.——The Atlanta School of Medicine opened for its regular session, September 14, with addresses by Dr. Thomas J. McArthur, Cordele, president of the Medical Association of Georgia, and others.

Personal.—Dr. George N. MacDonell has succeeded Dr. Odom O. Fanning, resigned, as superintendent of the Wesley Memorial Hospital, Atlanta.——Dr. James N. Brawner, head of the Atlanta Pasteur Institute, has started for Paris.——Dr. Charles J. Montgomery has been made professor of medical jurisprudence and hygiene in the Medical College of Georgia, Augusta, and Dr. J. A. Johnson has resigned from the faculty of the institution on accout of his removal to Nashville.

IOWA

Physician Wins Suit.—Dr. John D. Hullinger, Clinton, who was bound over to the grand jury in that city several weeks ago on the charge of having performed a criminal operation which resulted in the death of the patient, was freed from blame by the grand jury September 14.

Personal.—Dr. and Mrs. Frederick L. Appel, Muscatine, were painfully injured by the overturning of their automobile near Sweetland Center, September 21.——Dr. William Jepson, Sioux City, has returned from Europe.——Dr. Albert Chenoweth, Camanche, who has been ill with pleurisy, is reported to be convalescent.——Dr. George L. Everall, Clinton, is reported to be critically ill with cancer at Farmington, Ill.——Dr. and Mrs. Irenarch S. Buzard, Russell, start for Europe this month.

Health Boards to Meet.—The annual conference of state and local boards of health will be held at Des Moines, October 26 and 27. On the program appear the names of Clifford G. Roe, Chicago, assistant state's attorney, who will speak on the "White Slave Traffic," and Dr. Henry M. Bracken, secretary and executive officer of the Minnesota State Board of Health, who will present a paper on the "Quarantine of Smallpox." Dr. Fred Albert, Des Moines, secretary of the Iowa Association of Health Officers, requests that all local boards of health send their health officers to this meeting.

KANSAS

Physician Found Guilty of Contempt.—Dr. William S. Lindsey, Topeka, in charge of the cottages for the insane, adjacent to Christ Hospital, is said to have been found guilty of contempt of court by Judge A. A. Dana in the district court, October 2, for the violation of an injunction restraining Dr. Lindsey from receiving and treating insane patients at the cottages.

Contagious Diseases.—During August there was reported to the Kansas Board of Health, 294 cases of tuberculosis with 65 deaths, 351 cases of typhoid fever with 71 deaths, 54 cases of diphtheria with 7 deaths, 42 cases of scarlet fever with 4 deaths, 16 cases of smallpox with no deaths, and 35 cases of measles with 1 death. Tuberculosis, typhoid fever, diphtheria and measles were more prevalent, and scarlet fever and smallpox less prevalent than in the corresponding months of 1908.

KENTUCKY

Bequest.—By the will of the late Dr. William P. Wesselhoeft, Boston, Mass., Berea College receives a bequest of $5,000.

Personal.—Dr. John Todd has been elected a member of the Newport Board of Health.——Dr. Daniel J. Healey, Lexington, has been elected superintendent of the State Institution for Feeble-Minded Children, Frankfort, vice Dr. William L. Nuttall, Newcastle.

Physicians Organize.—At a meeting held in Covington, September 20, the Kenton-Campbell County Medical Examiners' Society was organized with an initial membership of ten. Dr. Charles E. Thompson, Covington, was elected president and Dr. William A. Young, Newport, secretary.

LOUISIANA

Sanatorium Notes.—Plans are being prepared by New Orleans architects for a new building for the Schumpert Memorial Sanatorium, to cost about $100,000, and to be located on the old Hicks homestead.——Dr. Charles Chassaignac has had plans prepared and has awarded the contract for the building of an annex to the New Orleans Sanatorium, to cost about $20,000.

Personal.—Dr. George Dock, New Orleans, has returned from Europe.——Dr. Charles M. Menville, Houma, has been elected president of the Terrebonne Parish Board of Health.——Drs. Walter F. Carstens and Warren G. Young have been appointed members of the New Iberia Board of Health.——Dr. Joseph J. Holt, New Orleans, has resigned as president of the Prisons and Asylums Commission.

Against Tuberculosis.—The Antituberculosis League of Louisiana has received a donation of $5,000 from an unknown individual. This will be used as the nucleus of a fund of from $40,000 to $50,000, to be used in establishing a shelter in New Orleans for consumptives.——Dr. Edward L. McGehee, New Orleans, president of the Antituberculosis League of Lousiana, gave an illustrated lecture at Garyville, September 14, at the close of which a branch of the state league was organized.

MARYLAND

Hospital Day.—Hospital Day, which was celebrated at Easton, September 30, was attended by about 4,000 persons. The proceeds go to the Emergency Hospital.

Charge Dismissed.—The charge of assault against Dr. R. Percy Smith, Pikesville, was dismissed at the trial, September 25, the plaintiff not appearing.

Financial Committee Appointed.—The Medical and Chirurgical Faculty of Maryland has appointed a committee to secure funds to pay off the debt on the building and also for its endowment.

One Instead of Two Boards.—Dr. John McPherson Scott, Hagerstown, secretary, and Dr. Herbert Harlan, Baltimore, president of the Board of Medical Examiners, suggest the advisability of having one board for the state instead of two, as obtain under the present medical law.

Baltimore

Library for Sale.—The library of the late Dr. Edward Z. Cole, which is said to be a unique collection, is offered for sale at public auction.

Fire in Hospital.—A fire occurred in the operating room of the Church Home and Infirmary, September 25, due to an explosion of chemicals, but the coolness and promptness of the physicians and nurses prevented panic, and confined the damage within small limits.

Jail Hospital.—A new hospital has been built, occupying three floors of the administration building at the jail, for the use of sick prisoners. It was opened October 1, and is well equipped, with one ward provided for tuberculosis patients, and one for infectious diseases. Dr. G. H. Waltereck, assistant to the jail physician, is in charge of the hospital.

Alumni Reunion Planned.—The delegates of Johns Hopkins Medical School to the Hopkins Alumni Council have appointed a committee composed of Drs. Thomas R. Brown, J. H. Mason Knox, Joseph H. Pratt, and J. Hall Pleasants to arrange plans for a reunion of the medical graduates some time during spring next year. It is intended to form an alumni association at this time.

Faculty Changes.—The following faculty changes in the Maryland Medical College are announced: Dr. Alexander D. McConachie has been made professor of diseases of the ear, nose and throat; Dr. William S. Love, professor of therapeutics; Dr. Irvin Ebaugh, professor of materia medica; Drs. Josiah S. Bowen and Frank J. Powers, associate professors of diseases of the ear, nose and throat, and Dr. A. C. Beethan, dispensary physician.

Home from Europe.—Drs. William H. Welch, Henry O. Reik, A. J. Neilson Reik, William S. Thayer, Lewellys F. Barker, Harvey W. Cushing, John S. Fulton, Thomas C. Worthington, William T. Watson and W. P. Miller have returned from Europe, where they attended the recent International Medical Congress at Budapest.——Drs. Harry Friedenwald, Frank Martin, Lillian Welsh, Mary Sherwood, Ridgeley B. Warfield, Thomas S. Cullen and William B. Wolf have returned from Europe.

Medical Colleges Open.—The Maryland Medical College, Baltimore, opened October 1. The opening address was delivered by Dr. E. Miller Reid on "The Age in Which We Live."——The University of Maryland, School of Medicine, opened October 1. ——The thirty-eighth annual session of the College of Physicians and Surgeons opened October 1.——The Woman's Medical College opened for its annual session October 1, and the Hospital of the Good Samaritan, which is connected with the institution, opened September 27, after having been closed for the summer.——Johns Hopkins Medical School opened for its annual session October 5.

Personal.—Dr. Adolph Meyer, professor of psychiatry in Johns Hopkins University, received the degree of LL.D. at the recent anniversary of Clark University, Worcester, Mass.—— Dr. Felix S. Jenkins is seriously ill at the home of his daughter in Towson, Md.——Dr. B. Bernard Browne, professor of gynecology in the Woman's Medical College of Baltimore, has resigned.——Dr. B. Bernard Browne, professor of gynecology in the Woman's Medical College, has resigned.——Drs. William H. Welch, Henry O. Reik, J. Neilson Reik, William S. Thayer, Lewellys F. Barker, Harvey Cushing, John S. Fulton, Thomas C. Worthington, William T. Watson, Clements von Pirquet, and W. P. Miller have returned from Europe.——Dr. Samuel Wolman has been appointed by the faculty of Johns Hopkins Medical School to inspect the sanitary condition of the boarding-houses occupied by students of that institution.——Dr. Hyman M. Cohen, associate editor of the *Maryland Medical Journal*, has resigned to enter the medical reserve corps of the Army.——Dr. Ira Remsen, president of Johns Hopkins University, was given the honorary degree of LL.D. at the convocation of Harvard University, October 7.——Dr. George M. Smith underwent an operation at Johns Hopkins Hospital, October 8.

MASSACHUSETTS

New Hospital Opened.—The new hospital at North Reading, for the treatment of tubercular patients, was opened recently. The sanatorium is one of three to be established by the state in different sections.

Sanatorium Site Acquired.—The New Bedford Antituberculosis Society has acquired by purchase five acres of land in the north end of the city on which will be established a tuberculosis sanatorium.

Bequest.—By the will of the late Charles H. Draper, Brookline, $1,000 each is bequeathed to the Children's Hospital and the New England Hospital for Women and Children, Boston. ——By the will of the late Katherine T. Buttrick, Lowell, a bequest of $20,000 is made to St. Johns Hospital, Lowell, and also one of $6,000 to maintain a free bed.——By the will of the late Albert T. Whiting, the first health officer of Boston, who died October 1, $4,500 is devised to the Children's Hospital, Boston.

Council Meeting.—The stated meeting of the Massachusetts Medical Society was held in John Ware Hall, Boston Medical Library, October 6. Dr. J. Bapst Blake, Boston, was elected delegate to the American Medical Association in place of Dr. John L. Morse, Boston, who resigned, as he desired to be more nearly identified with section work. Dr. Charles H. Cook, Natick, resigned from the committee on state and national legislation on his appointment as a member of the Massachusetts Board of Registration in Medicine, and Dr. David D. Scannell, Boston, was selected to succeed him. The following delegates to the American Medical Association were appointed for 1910 and 1911: Drs. Horace D. Arnold, Boston; Homer Gage, Worcester; Orlando J. Brown, North Adams, and alternate delegates, Drs. Frederick J. Cotton, Boston, Francis W. Anthony, Haverhill, and William A. Dolan, Fall River; and the following delegates to state societies: To Vermont—Drs. James H. Higgins, Marstons Mills, and Granville S. Allen, Lawrence; to New York—Drs. Samuel B. Woodward, Worcester, Frank A. Hubbard, Taunton; to Maine—Drs. Edward W. Taylor, Boston, and George Z. Goodell, Salem; to New Hampshire—Dr. Ernest S. Jack, Melrose; and to Connecticut—Drs. Frederick S. Ward, Springfield, and George P. Twitchell, Greenfield. It was voted that all fellows of the society who are members of any standing committee of the American Medical Association or of the National Legislative Council, and delegates or alternates to the Association be invited to all meetings of the Council of the Massachusetts Medical Society. This vote was passed with the object of more closely cementing the business aims and methods of the state organization and those of the American Medical Association, bringing about better understandings and results. It was also decided that the annual discourse, when delivered, should be the property of the state society. The council, taking up the matter of minority and majority reports of the committee on contract work, voted that the matter be indefinitely postponed.

MICHIGAN

Sanitation on Trains.—Dr. F. W. Shumway, Lansing, secretary of the State Board of Health, announces that he is about to call a meeting of the representatives of all railroads doing business in the state to discuss the provisions of the new law giving the board authority to require sanitary precautions on passenger trains for the protection of the public.

Hospital Opens Outdoor Department.—On September 8, Butterworth Hospital, Grand Rapids, established a free medical dispensary in the basement of the institution, with six rooms. The dispensary will be open from 12:30 to 2 daily. Mondays and Thursdays will be devoted to diseases of the eye, ear, nose and throat; medical and surgical cases will be cared for Tuesdays and Wednesdays and Fridays, and skin diseases will be treated on Saturday.

NEW HAMPSHIRE

McCormack in New Hampshire.—Dr. J. N. McCormack, chairman of the organization committee of the American Medical Association, began a campaign in New Hampshire October 3, and will visit all counties in the state.

State Sanatorium Opens.—The first patients to be received at Glencliff, the State Sanatorium for Tuberculosis, arrived September 11. The present capacity of the institution is forty patients, and examinations for admittance are to be held in Manchester.

Society Meeting.—At the annual meeting of Sullivan County Medical Society, held in Claremont, the following officers were elected: President, Dr. Edwin C. Fisher, Sunapee; vice-president, Dr. Fred P. Claggett, Newport; secretary, Dr. Emery M. Fitch, Claremont; treasurer, Dr. David M. Currier, Newport, and censors, Drs. Albion S. Marden, Newport, Oscar C. Young, Charlestown, and Henry C. Sanders, Claremont.

Money for Hospitals.—A legacy of $5,000 to the Mary Hitchcock Hospital, Hanover, is contained in the will of the late Stephen M. Crosby, Boston. The bequest is to endow a bed in memory of the testator's father, Nathan Crosby, preference to be given, if possible, to graduates of Dartmouth College.——Proceeds of a tag day, held in Portsmouth, August 7, for the benefit of the Cottage Hospital, are expected to amount to $2,000.

Crisis in Hospital.—As the result of trouble at Elliot Hospital, Manchester, between the medical staff and the matron, Drs. William M. Parsons, L. Melville French, George D. Towne, Henry D. W. Carvelle, Hosea B. Burnham, William H. Pattee, Charles F. Flanders, George M. Watson, Clarence W. Milliken, J. Franklin Robinson, David W. Parker, Arthur F. Wheat, Henry W. N. Bennett, Frank N. Rogers, Clarence O. Coburn, Ezra A. Jones, John C. O'Connor, and Emdon Fritz have resigned from the staff. The trustees have placed Dr. George C. Wilkins in charge of the medical and surgical department of the hospital, and Dr. Charles A. Sturtevant at the head of the maternity ward. These gentlemen have been authorized to choose assistants.

NEW YORK

Medical College Opens.—Albany Medical College enters on its seventy-ninth year, September 21. The introductory lecture was delivered by Dr. Frederick C. Curtis.

District Society Meeting.—The Sixth District Branch of the Medical Society of the State of New York held its third annual meeting in Oneonta, September 28. Dr. Frank DeW. Reese, Cortland, was elected president, and Dr. Herbert W. Fudge, Elmira, was reelected secretary-treasurer.

Railway Surgeons to Meet.—The New York and New England Association of Railway Surgeons will hold its nineteenth annual meeting at the Academy of Medicine, New York City, November 16 and 17. A symposium will be presented on "Causes of Railway Accidents Individualized."

New Tuberculosis Hospital.—The committee on tuberculosis hospital of the Ontario County board of supervisors has recommended the approval of the plans for the hospital, which call for a central building with wings attached, with open-air sleeping quarters. The institution is to be known as Oak Mount.

Open-Air Schools.—Rochester (N. Y.) has opened an open-air school for children suffering from incipient tuberculosis. Twenty children have been enrolled. They will have desks in a big tent, will be wrapped up warmly and will have their legs in bags to protect them from the cold.——Buffalo is also contemplating a similar school. School No. 14 has been designated as a school where the children of different mentality from those in all other schools will be taught by teachers especially trained for this purpose.

New York City

Clinic for Naval Surgeons.—At the invitation of the trustees of Roosevelt Hospital the surgeons of the German, French, English and Italian visiting warships attended a surgical clinic in the Syms operating theater of the hospital. The visitors were entertained by Dr. George E. Brewer and his associate, Dr. Charles H. Peck.

Returned from Europe.—Dr. Alexis Carel of Rockefeller Institute arrived home from Europe on October 1. During his stay in Paris he delivered several lectures on surgery.——Dr. William J. Robinson, Dr. and Mrs. Ludwig W. Kast, Dr. Smith Ely Jelliffe and family, Drs. Frederick Peterson, Frederick Earle Beal, and Valentine Mott have returned from Europe.

The Milk Essay Competition.—The department of health has received nearly one hundred essays in the prize competition on the care of dairy cows and the preparation of milk for the New York city market. The prizes will be finely bred dairy cows. Dr. Darlington has taken this way of interesting the milk producers in the New York City production territory in the requirements of the City Health Board. The prize essays will be distributed among the dairymen.

Health Home Closed.—This home at Coney Island has closed for the season after having given outings to 720 mothers and 1,652 children and day excursions to 1,652 mothers and 2,351 children. The Chappaqua Convalescent Home, the Children's Summer Home at Bath Beach, the Boy's Camp near Stamford, and the Martha Home at Ossining swelled the number of those cared for to 11,530. In addition the Sick Children's Mission treated more than 2,000 children in their homes in the city.

Bequests.—The will of Miss Phebe Ann Thorne gives the Home for Incurables $10,000; the Woman's Hospital, $10,000; the Society for the Relief of the Ruptured and Crippled, $10,000; the General Memorial Hospital, $10,000; the Manhattan Eye and Ear Hospital, $5,000; the New York Eye and Ear Infirmary, $5,000; the New York Skin and Cancer Hospital, $10,000; and the Colored Home and Hospital, $5,000. ——Mrs. Emily A. Gere has bequeathed $30,000 in trust to a servant and the testator's niece, who will receive the income as long as they live, and at their death this money is to go to the St. Rose Free Home, a cancer hospital.

Medical Schools Open.—The entering class of the University and Bellevue Hospital Medical College promises to be larger than that of last year. Chancellor Henry M. MacCracken made the opening address to the students and announced that the Carnegie Laboratory would be enlarged at a cost of about $100,000. He also announced that the college had been the recipient of a bequest of $25,000 in a will not yet probated. ——The one hundred and first annual session of the College of Physicians and Surgeons of Columbia University opened September 23, with an enrollment of 279. President Nicholas Murray Butler delivered the address of welcome, and Dr. Christian A. Herter, professor of pharmacology and therapeutics, spoke on "Imagination and Idealism in Medical Science."

OREGON

Eastern Oregon Physicians Meet.—At the annual meeting of the Eastern Oregon Medical Association, held in Pendleton, September 28 and 29, the following officers were elected: President, Dr. Robert E. Ringo, Pendleton; vice-presidents, Drs. Frank B. Kistner, Heppner, and E. O. Logan, The Dalles; secretary-treasurer, Dr. Roy C. McDaniel (reelected), Baker City; and censors, Drs. Thomas M. Henderson, Pendleton, Jacob Prinzing, Ontario, and Oliver M. Dodson, Baker City.

PENNSYLVANIA

Physicians Violate Law.—Sixty physicians of Schuylkill county were placed under arrest October 2 by Dr. R. J. Brauner, State Health Inspector, charged with the violation of the act which requires the recording of births within ten days. The defendants are among the most prominent physicians in the county.

Memorial Addition to Hospital.—Mrs. John T. Dyer has planned to erect a new wing at the Charity Hospital, Norristown, as a memorial to her late husband. One section of the new building will be used for the treatment of diseases of the eye, ear, nose and throat, and the other section of the building will be used for the care of medical and surgical cases.

Railroad Fatalities.—The Pennsylvania Railroad issued on October 9, statistics showing that the number of deaths due to trespassing on railroad property in the United States in the last ten years reached 47,416. The report shows that the number of persons injured aggregated 50,000. In 1898, the number of trespassers who lost their lives on American railroads was 4,063, five years later the number was 5,000, and in 1907 the number killed reached 5,612, or more than 15 a day. In 1899, 465 trespassers lost their lives on the Pennsylvania lines; in 1904, the number killed was 781, while in 1907 the fatalities reached 915, an average of almost 3 for every business day in the year. In the ten years prior to

Jan. 1, 1909, 7,240 persons were killed on the Pennsylvania system, and during the first six months of the present year, 285 trespassers were killed. The report shows that it is not only tramps who are victims, but men of the laboring class, factory workmen, their wives and children, who use railroad tracks as thoroughfares.

Philadelphia

Officers Elected.—The following officers have been elected to serve during the ensuing half year of the Southwark Medical Society: President, Dr. Max Staller; vice-president, Dr. Aaron Brav; secretary, Dr. Maurice B. Cooperman; treasurer, Dr. Nathan Blumberg.

Loving Cup for Dr. Dixon.—In appreciation of his splendid work in the State Department of Health, Dr. Samuel G. Dixon, State Health Commissioner, was presented with a beautiful silver loving cup by the county medical inspectors of the state and chiefs of the state tuberculosis dispensaries, at a meeting held in this city, October 5.

To Enlarge Hospital.—A contract has been awarded for the erection of a five-story addition, 25x78 feet, to the Samaritan Hospital at the northeast corner of Broad and Ontario streets. The new structure will be a modern fire-proof building, provided with dispensaries, wards and operating-room, and will be erected at a cost of several thousand dollars.

Personal.—Dr. Gerald O'Farrell was thrown from his carriage and sustained a fracture of the collar-bone, October 5. ——Dr. William E. Robertson has been appointed professor of theory and practice of medicine in the Medical Department of Temple University, vice Dr. Samuel Wolfe, resigned.—— Dr. Howard S. Anders has returned from Europe.

The New Home of the College of Physicians to Open.—The new building of the College of Physicians at Twenty-second and Ludlow streets will be dedicated with appropriate ceremonies on Wednesday, November 10. Delegates and guests are requested to register as soon after their arrival as possible. Guests, officers and fellows will assemble at the First Unitarian Church, Twenty-second and Chestnut streets, at 2 p. m., and candidates for associate fellowship, the guests of the occasion and the officers of the college are requested to appear in academic costume.

State Health Inspectors Meet.—The second annual meeting of the county medical inspectors and chiefs of the tuberculosis dispensaries of Pennsylvania was held in this city October 5 and 6. The conference was called by Dr. Samuel G. Dixon, Harrisburg, the State Health Commissioner. One hundred and fifty physicians were in attendance. Tuberculosis and the latest methods of fighting it was the main theme of the various meetings. Every phase of the work of the State Health Department was discussed at an assembly meeting held in the Academy of Natural Sciences. Among the speakers were: Commissioner of Health of the State of New York Dr. Eugene H. Porter and the Commissioner of Health of New York City, Dr. Thomas Darlington. The meeting was also addressed by Surgeon-General of the Marine-Hospital Service Dr. Walter Wyman. The program further included clinics on tuberculous meningitis, by Dr. Joseph Sailer, in the Philadelphia General Hospital; surgical tuberculosis, by Dr. Robert G. LeConte, in the University of Pennsylvania Hospital; visceral tuberculosis, by Dr. James M. Anders, at the Medico-Chirurgical Hospital, and tuberculosis of serous membrane, by Dr. James C. Wilson, at the Jefferson Hospital. The conference came to a close by a luncheon given by Dr. Dixon at his country estate, Black Rock Farm.

SOUTH CAROLINA

Improvements in Medical College.—The Medical College of the State of South Carolina, Charleston, opened for the year October 4. A special course of five lectures on "Uncinariasis" is to be delivered by Dr. Charles W. Stiles, U. S. P. H. and M.-H. Service, in December. The college building has been remodeled since the close of the session in last May. An assembly hall takes the place of the old amphitheater, two additional lecture rooms have been constructed and a new physiologic laboratory has been provided and equipped.

Faculty Changes.—The Medical College of the State of South Carolina announces the following changes in its faculty: Dr. A. Robert Taft, lecturer on materia medica; Dr. E. H. Sparkman, assistant to the chair of pathology; Dr., Daniel L. Maguire, assistant in surgery; Dr. Richard M. Pollitzer, instructor in laboratory physiology; Dr. Thomas W. Reynolds, assistant to the chair of obstetrics; Dr. Charles A. Speisseger, assistant to the chair of chemistry; Dr. Francis L. Parker, Jr., lecturer on medical jurisprudence; and Mr. J. B. Hyde, assistant to the professor of pharmacy.

SOUTH DAKOTA

Personal.—Dr. Charles F. Holmes, Hecla, who was seriously injured in an automobile accident recently, is said to be convalescent.

State Medical Society Meeting.—The twenty-eighth annual session of the South Dakota State Medical Association was held in Aberdeen, September 29 to October 1. The following officers were elected: President, Dr. Thomas B. Smiley, Mount Vernon; vice-presidents, Drs. Hans M. Finnerud, Watertown, and William G. Smith, Sturgis; and secretary-treasurer, Dr. Robert D. Alway, Aberdeen. The next meeting of the society will be in Hot Springs.

TEXAS

Adjudged Insane.—Dr. William R. Mercer, Galveston, is said to have been adjudged not responsible and requiring restraint, September 11.

Found Not Guilty.—In the case of Dr. Hake, Hubbard City, charged with the illegal writing of prescriptions for alcoholic liquors, the jury at Hillsboro returned a verdict of not guilty, September 14.

Healers Must Be Licensed.—The attorney-general has furnished a ruling to a firm of physicians in Killeen, holding that magnetic healers come within the provisions of the "one board" medical act, and that any one practicing through magnetic healing, massage, manipulation of the body, etc., with a view of curing diseases, must have a license.

Medical Colleges Open.—The State Medical College, Galveston, opened October 1. Dr. Arthur E. Austin delivered the opening address on "The Doctor in Fiction."——The Southwestern University Medical Department, Dallas, opened without formal exercises September 29.——Baylor University Medical College, Dallas, opened with informal exercises September 29. The college occupies new quarters in the science building.

UTAH

Automobile Accident.—Dr. Frederick Stauffer, Salt Lake, and Drs. Amasa S. Condon, Ezra C. Rich and Robert S. Joyce, Ogden, were seriously injured, at Ogden, September 21, by the overturning of an automobile in which they were riding.

Smallpox.—Reports sent in to the State Board of Health state that in one small town in Rich county there are more than thirty cases of smallpox. These yearly outbreaks are said to be due to the local prejudice against vaccination.

State Society Meeting.—The fifteenth annual meeting of the Utah State Medical Association was held in Ogden September 21 and 22. The following officers were elected: President, Dr. Joseph S. Richards, Salt Lake City; vice-presidents, Drs. Amasa S. Condon, Ogden; Walter T. Hasler, Lehi, and Ernest D. Hammond, Salt Lake; secretary, Dr. W. Brown Ewing, Salt Lake; treasurer, Dr. James N. Harrison, Salt Lake; councilor and delegate to the American Medical Association, Dr. A. C. Bailey, and alternate delegate, Dr. Robert S. Joyce, Ogden. Salt Lake City was selected as the place of meeting for 1910.

VIRGINIA

Changes in Examining Board.—The following changes in the membership of the State Board of Medical Examiners are announced: First district, Dr. Joseph N. Barney, Fredericksburg; third district, Dr. J. E. Wright, Brook Hill; fourth district, Dr. Otho C. Wright, Jarratt; sixth district, Dr. Henry W. Dew, Lynchburg; seventh district, Dr. Philip W. Boyd, Winchester; and tenth district, Dr. Robert Glasgow, Lexington.

Medical Society Meeting.—At the fortieth annual session of the Medical Society of Virginia, held in Roanoke, October 5 to 7, the following officers were elected: President, Dr. Elliott T. Brady, Abingdon; vice-presidents, Drs. Walter A. Plecker, Hampton, James S. Irvin, Danville, and R. H. White, of the University of Virginia; secretary, Dr. Landon B. Edwards, Richmond (reelected); treasurer, Dr. Robert M. Slaughter, Theological Seminary (reelected); delegates to the American Medical Association, Drs. John S. Horsley, Richmond, Thomas C. Firebaugh, Harrisonburg, and William E. Anderson, Farmville, and councilors at large, Drs. Edward McGuire, Richmond, Richard W. Fry, Roanoke, Stephen Harnsberger, Catlett, M. M. Pearson, Bristol, George J. Tompkins, Lynchburg; first district, Dr. Clarence P. Jones, Newport News; second district, Dr. Edward E. Field, Norfolk; third district, Dr. Alfred L. Gray, Richmond; fourth district, Dr. Samuel A. Hinton, Petersburg; fifth district, Dr. Jesse M. Shackelford, Martinsville; sixth district, Dr. Sparrell S. Gale, Roanoke; seventh district, Dr. William P. McGuire, Winchester; eighth district, Dr. Tunis

C. Quick, Falls Church; ninth district, Dr. John T. Graham, Wytheville; and tenth district, Dr. Samuel H. Burton, Parnassus. An interesting incident of the session was the presentation of a purse of $1,000 in gold to Dr. Landon B. Edwards, Richmond, who has been secretary for many years. The presentation was made by Dr. Paulus A. Irving, Richmond. It was decided to increase the dues of the society from $2 to $3 per annum. A resolution was passed endorsing the senate bill to increase the salary of the Public Health and Marine-Hospital Service. The next meeting is to be held in Norfolk.

WISCONSIN

Personal.—Dr. A. Hamilton Levings, Milwaukee, has returned from abroad.——Dr. J. M. Beffel, Milwaukee, secretary of the Wisconsin State Medical Society, who was arrested for leaving his automobile standing in front of his home in Milwaukee, in violation of a city ordinance, was found not guilty.

Pasteur Institution.—Final arrangements are being made by the State Board of Health to establish an institute for the treatment of hydrophobia in connection with the state hygienic laboratory, Madison. Treatment will be given free of charge to indigent persons, but a small amount will be charged persons who are able to pay for the treatment in order to make the work as nearly self-supporting as possible.

Antituberculosis.—The Antituberculosis Association of Wisconsin is thoroughly organized and promises a vigorous campaign on the lines of increasing membership, raising of funds, promoting bills in need of legislation, and direction of sanatoria in different parts of the state. Prof. W. D. Frost, Wisconsin University, who has written and lectured extensively on tuberculosis, is president of the association, and Lester W. Hutchcroft, of the State Board of Health, is secretary.

GENERAL NEWS AND COMMENT

Anderson Made Chief of Hygienic Laboratory.—Passed Assistant Surgeon John F. Anderson, P. H. & M.-H. Service, has been appointed director of the hygienic laboratory of the service, vice Surgeon M. J. Rosenau.

Personal.—Dr. C. A. Dawes, M. R. C. U. S. Army, was taken ill with appendicitis while on a practice march from Fort Perry, Ohio, to Fort Thomas, Ky., October 1.——Dr. John Mason Little, Jr., Boston, narrowly escaped death in the wreck of the Princeton mission boat, *Andrew J. McCosh*, in the straits of Belle Isle, Sept. 12, but was rescued by Dr. Grenfell.

Medical Officer May Command Ship.—The attorney general has handed down an opinion to the secretary of the navy that he has authority to assign a medical officer not below the grade of surgeon to the command of a naval hospital ship. This decision has been made in view of the expected commission of the hospital ship, *Solace*, for which the Chief of the Bureau of Medicine and Surgery desires to ask the detail of a member of the medical department as commanding officer.

Conference on Prevention of Infant Mortality.—The American Academy of Medicine, at the mid-year meeting, will hold a conference on the prevention of infant mortality at New Haven, Conn., November 11-12. The first session will consider the "Medical Prevention of Infant Mortality;" the second will take up the "Philanthropic Prevention of Infant Mortality;" the third will deal with the "Institutional Prevention of Infant Mortality;" and the fourth will be devoted to discussion of the "Educational Prevention of Infant Mortality."

Postponement of International Congress of School Hygiene.—The third international congress for school hygiene, which was to have been held next March, has been postponed until August 2 to 7, 1910, in order to give more importance to the exhibition to be attached to the congress. A pamphlet of 60 pages, giving the details of the congress, will be sent on demand to the secretary, Dr. Dufestel, 10 Boulevard Magenta, Paris, France. The honorary president of the committee of propaganda in this country is Dr. A. T. Cabot, of Boston, with Dr. J. H. Musser, of Philadelphia, as president, and Dr. T. A. Storey, of Boston, Mass., as secretary and treasurer.

Military Surgeons' Meeting.—At the eighteenth annual meeting of the Association of Military Surgeons of the United States, held in Washington, October 5 to 8, the following officers were elected: President, Colonel Joseph K. Weaver, N. G. Pa., Norristown, Pa.; first vice-president, Colonel William C. Gorgas, M. C., U. S. Army, Ancon, Canal Zone, Panama; second vice-president, Surgeon Charles P. Wertenbaker, P. H. & M.-H. Service, Norfolk, Va.; third vice-president, Surgeon William C. Braisted, U. S. Navy, Washington, D. C.; secretary, Major Charles Lynch, M. C. U. S. Army, Washington, D. C.; and treasurer, Major Herbert A. Arnold, N. G. Pa., Ardmore, Pa. It was decided to hold the 1910 meeting in Richmond, Va.

Prevention of Contamination of Vegetables.—It is interesting to note that supervision of vegetable gardens is suggested in San Francisco as necessary to prevent the contamination of their products with amebas from the human excrement used as a fertilizer by the Chinese gardeners. According to H. W. Austin (*Public Health Reports*, Sept. 24, 1909), of 55 cases of amebiasis occurring in the Marine Hospital at San Francisco from Dec. 1, 1908, to Aug. 9, 1909, 16, it is believed, originated in California. It has been decided by the San Francisco board of health to declare amebic dysentery an infectious disease and require it to be reported. The occasional occurrence of this disease in the Northern states indicates that precautions to prevent its spread would not be untimely.

Appeal for Data in Regard to Influence of Roentgen Exposures on Growth.—In experimentation on young animals, the Roentgen rays have displayed a detrimental influence on the growth, and the German Roentgen Society is now making a collective inquiry to determine whether this occurs also in children exposed to the rays. The question blank sent out by the society asks the number of children thus treated, age, region exposed, pathologic reason for the exposures, length of exposures, soft or hard tubes (5-7 Wehnelt or 7.5 to 9 Wehnelt), year of exposure, number of children examined since, and, if any evidence of interference with growth was detected, details of such influence. The interference with growth may not become apparent until after a number of years, so all children exposed at any time should be included in the investigation. On suspicion of checked growth of the extremities, comparative skiagraphs and measurements should be made. Replies may be sent to Dr. Försterling, Mors, Rheinland, Germany, chairman of the committee in charge of the inquiry, or to Prof. P. Krause, Bonn, president of the Röntgengesellschaft.

The Far-Eastern Association of Tropical Medicine.—The Far-Eastern Association of Tropical Medicine will hold its first meeting in Manila, March 14, 1910. This association was formed two years ago by representatives from Japan, China, Siam, the Straits Settlements, Ceylon, Hongkong, French Indo-China, and the Philippine Islands, present at a meeting of the Philippine Islands Medical Association. Dr. Paul C. Freer, of Manila, was elected president and Dr. Francis Clarke of Hongkong, general secretary. The Governor General of the Philippine Islands subsequently invited the representatives of the various governments within the territory of the association to send delegates to the first meeting to be held in Manila. Cordial adherence to the purposes of the association was expressed by all who were so addressed and active interest in the formation of the various sections was manifested. The government of the Philippine Islands made an appropriation to cover the expenses of the meeting and a preliminary program of sessions was issued. The sections are divided as follows: protozoology and helminthology; cholera, plague and leprosy; surgery and obstetrics; diseases of children; fevers in the tropics, including malaria, typhoid, etc.; dysenteries; beriberi; tuberculosis; climate, hygiene and sanitation. The first six sessions will be held in Manila, the remainder at Baguio, the summer capital of the islands, in the Benguet Mountains. The new government hospitals and the new buildings of the Philippine Medical School will be dedicated at the time of the meeting. The interest manifested by the various countries in the Far East, and the replies already received insure papers of the highest class and a large attendance. The meeting will be held during the best time of the year. The opportunity for seeing Manila and its various modern scientific institutions, as well as portions of our Philippine possessions under the best auspices, will be unexcelled. Physicians making the journey to Japan or around the world can easily arrange the short side trip from Hongkong to Manila. Steamship communication between the two ports is established by the regular Hongkong-Manila lines twice a week and by the vessels of the North German Lloyd's Australian line, the Nippon Yusen Kaisha and the China and India Navigation Company; the Australian boats are all of good size and of the best class. The large vessels of the Pacific Mail now also stop at Manila, going to the latter port direct from Japan. The workers in medical science in the Far East have made such rapid advances in the past few years that encouragement of their new venture, which has for its purpose the advancement of medical research in this most important area of the world, would most certainly reflect credit on the medical profession as a whole. Interest in tropical medicine is increasing rapidly in this country and the time is not far distant when chairs of Tropical Medicine will be established in some of our medical schools. There is no better way to acquire a knowledge of the work to be undertaken than by sending representatives to this meeting, and it is hoped that some of our larger institutions may be able to do this.

CANADA

Tuberculosis Sanitaria.—The Ontario government was recently asked to erect, equip and maintain, by a large provincial delegation of medical and laymen, sanitaria for indigent and other consumptives. In replying to the propositions of the delegation the premier, Sir James Whitney, stated he would be in favor of withdrawing the annual provincial grant to those general hospitals throughout the province which refused to take such patients. The premier thought that there was too much "scare" about consumption, but promised that the proposals of the deputation should receive the careful consideration of his cabinet.

Public Health in Montreal.—Montreal is engaged in municipal reorganization and there is now a movement on foot to have the department of health controlled by five physicians, who shall be paid an annual salary for their services. A health committee composed of aldermen, oftentimes new at that, is not by many considered satisfactory, as they have no knowledge of medical matters.——Public vaccination has been resumed in Montreal after a discontinuance of several days. Two children who had been vaccinated had died of tetanus and the provincial board of health were required to test the vaccine. Careful tests failed to discover anything wrong with the vaccine.

Hospital News.—The Protestant Hospital for the Insane at Verdun, Quebec, has just completed a new wing for the accommodation of 150 patients. There are at the present time 614 patients in this hospital.——The Montreal General Hospital will shortly commence the erection of a new pathologic department, which will not be surpassed by any similar one on this continent. A large addition to the main hospital building is also being projected. A bond issue of $200,000 for the purpose has been ordered. During the past six months 1,567 patients were treated indoors; in the outdoor, 25,063. During that period legacies had been received to the amount of $7,700. The income was $59,059 and the disbursements amounted to $65,245.

Interprovincial Registration.—This subject was discussed at a special meeting of representatives of the four western Canadian provinces, Manitoba, Saskatchewan, Alberta and British Columbia at Banff, Alta., on the 28th. Dr. Spankie, a member of the Ontario Medical Council, was present, which shows that the Ontario Medical Council is at last awake to the advantages of having interprovincial reciprocity with these provinces. A meeting of the executive council of the Canadian Medical Association is to take place at Toronto on the 11th inst., when a special committee will be appointed on dominion registration; and the provincial medical councils will be asked to appoint a representative on this special committee. The feeling is such amongst the medical profession of Canada at the present time, that it is thought that dominion registration will very soon be an established fact. It is expected that some new legislation will be enacted at the coming session of Parliament which will pave the way for dominion registration.

Personal.—Dr. Thomas G. Roddick, Montreal, sailed from Rotterdam on the 2d of October.——Drs. Alexander McPhedran, W. Henry B. Aikins, Herbert J. Hamilton and Herbert A. Bruce, Toronto, have returned from attending the International Medical Congress at Budapest.——Drs. Richard A. Reeve and Perry G. Goldsmith, Toronto, are in New York.——Dr. Robert H. Craig, Montreal, has returned from Europe.——Dr. Walter H. McKeown, Toronto, after attending the Canadian Medical Association at Winnipeg, returned home, going around via Vancouver, San Francisco, Denver and Chicago.——Dr. William A. Young, Toronto, managing editor of the *Canadian Journal of Medicine and Surgery*, whilst abroad in Europe, was elected president of the American Medical Editors' Association.——Drs. D. J. Gibbs Wishart (chairman), Allen M. Baines, James F. W. Ross, Charles J. Hastings, R. W. Bruce Smith, the president, Dr. Adam H. Wright, and General Secretary Dr. George Elliott are the committee of arrangements for the forty-third annual meeting of the Canadian Medical Association to be held in Toronto on the 1st, 2d, 3d and 4th of June, 1910.——Dr. John N. E. Brown, superintendent of the Toronto General Hospital, and Dr. R. W. Bruce Smith, inspector of hospitals for Ontario, have returned from attending the meeting of the American Hospital Association in Washington, D. C.——Dr. Brodie, the new professor of physiology in the medical department of the University of Toronto, delivered the opening lecture of the medical session this year.——Dr. W. O. Walker has been appointed associate professor in Queen's University, Kingston.——Dr. S. E. Wolbach has been appointed director of the histologic laboratory of McGill University.

FOREIGN

A Physician Made Governor in Siberia.—The large peninsula of Kamchatka, in northern Siberia, has recently been organized into a separate territory, and a physician, Dr. W. Perfiljew, installed as the first governor.

London School of Tropical Medicine.—This institution is to be formally opened Tuesday, October 26. The American ambassador has promised to preside at the opening meeting and an address will be delivered by Dr. Osler. At the school dinner which is to be held at the Savoy Hotel the same evening, Dr. A. G. Bagshawe, director of the Sleeping Sickness Bureau, will preside.

The International American Congress of Medicine and Hygiene.—This congress will be held at Buenos Ayres, May 25, 1910, during the celebration of the centennial of the independence of the Argentine Republic. An international exposition of hygiene is also to be held in connection with the congress, to remain open for six months. Details of the congress, rates, etc., may be obtained from the general secretary, Luis Agote, Medical Faculty, Buenos Ayres, Argentine Republic. There are nine principal sections, including one on sanitary technology, veterinary police, and dental pathology, in addition to the sections on medicine, surgery, biology and public hygiene. The dean of the medical faculty, E. Canton, is president of the organizing committee. Among the special subjects to be discussed are the raising of the standards for medical education, subtropical pathology, hygiene and prophylaxis, malaria and tuberculosis.

The Mexican Prophylactic Society.—The first anniversary of its foundation was recently celebrated by the Mexican *Sociedad Sanitaria y Moral de Profilaxis de las Enfermedades Venereas*, and the work of the year reviewed. A Spanish translation of Fournier's pamphlet, "For Our Sons When They Are 18," was published by the society and large numbers distributed; a second edition was published at the expense of the national army and navy department, and a third edition by the department of agriculture. Regular monthly meetings have been held at Mexico City and various problems of moral prophylaxis discussed, the reports with other original articles appearing in the *Cruz Blanca*, the organ of the society. A special free dispensary for men with venereal diseases has been opened, and lectures have been delivered in the law and engineering schools on the dangers of venereal disease. Dr. J. G. Uruena of the City of Mexico is secretary of the new society.

Prizes Awarded at the International Medical Congress.—As already mentioned, the trachoma prize was not awarded, but the $1,000 prize founded in 1897, by the City of Moscow, was given to O. Hertwig, professor of anatomy and comparative embryology at Berlin, and one of the publishers of the *Archiv für mikroskop. Anatomie und Entwicklungsgeschichte*. The City of Paris prize of $600 was awarded to the serologist, J. Bordet, of Brussels, of complement-deviation fame. The Lenval prize of $80 was divided between Prof. H. Neumann, of Vienna, and Dr. A. Grey, of Glasgow, at the international otology congress which also met at Budapest. It was decided that the international medical congresses should henceforth not be held oftener than once in four years, so that the next congress will not convene until 1913, when it will meet in London. The international committee appointed to prepare the preliminaries for the international medical congresses in future is to have its headquarters at the Hague, near which the secretary, Prof. K. Wenckebach, resides. The members of the committee are Professor Pavy of London, Blondel of Paris, as president and vice-president; the latter is also secretary of the International Medical Press Association, Maragliano of Genoa, Müller of Budapest, and Waldeyer of Berlin. An international association for the study of epilepsy was also organized before the close of the congress, about thirty members forming the provisional international board, including Obersteiner, Oppenheim, Tamburini, Donath and Turner.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Oct. 2, 1909.

Campaign Against Nostrums

It seems that at last the government is waking up to the evils of the unrestricted sale of nostrums in this country. Some time ago, as reported in a previous letter, the General Medical Council appointed a committee to consider the question of unqualified practice, and this body began by investigating the regulations for the control of such practice which exist in other countries. A most valuable and exhaustive report on these regulations was presented to the privy council and the government has decided next session to appoint a royal commission to consider the sale of nostrums. It is thought that this commission is likely to recommend legislation similar to that which exists in many other countries, that the vendors of nostrums will be compelled to disclose on the label the ingredients which enter into their composition. For some time the *British Medical Journal* has been publishing in a series of articles the composition of all the nostrums in the market and the cost of the ingredients. Preparations which are claimed to be infallible cures for all sorts of ailments are shown to be composed of very ordinary ingredients which cost a minute fraction of the price asked. The extent of the nostrum evil in this country is shown by the following figures: Every article sold must bear a government stamp for the year ending March 31, 1908. The revenue derived from these stamps amounted to $1,600,000; the number of articles stamped was 41,757,575, for which it is estimated the public paid $12,000,000. The struggle is certain to be a long and difficult one. The large financial interests involved will obtain very powerful support in several directions. Extensive advertising has rendered the lay press very subservient; even leading journals are not ashamed to publish puffs disguised as editorials. In attacking the nostrum evil another form of opposition will also be encountered. All the various cranks—antivivisectionists, antivaccinationists, Christian scientists, etc.—who entertain extreme views on the liberty of the subject, will oppose any state interference with the sale of nostrums and will represent it as being purely in the interests of the medical profession.

Beriberi in England

At Newcastle-on-Tyne as many as 25 cases of beriberi have been reported. They occurred among the men of the Brazilian warship *Barossa.* One death has occurred, 4 patients have been discharged, and 20 remain in the hospital. The cases bear out the rice hypothesis of the disease, for the Brazilians are rice eaters and the patients had eaten this food three times a day. The health officer, Dr. Harker, has expressed the view that the spread of the disease was due to the sailors converting the forecastle into an incubator by closing the ventilators and lighting stoves.

Malaria Prevention in India

The government of India has decided to take vigorous steps for the prevention of malaria and has ordered a conference to be held on the subject at Simla on October 11. Discussing the question in the *Times*, Major Ross thinks that for rural areas quinin prophylaxis, assisted if possible by screening, is the best measure. For towns and crowded areas opinion is divided; some advocate the same measures here also but others prefer mosquito reduction. The latter has the great advantage that it tends to reduce other mosquito-borne diseases, such as filariasis, which abounds in parts of India. On the other hand, quinin prophylaxis has many disadvantages. Merely to sell or give quinin at dispensaries and post-offices is not sufficient, because the poor cannot afford the time to attend constantly for small doles of the drug. For this measure to be effective the drug must be distributed gratis from house to house for long periods and the occupants must be urged to take it. Some writers claim, however, that in India quinin prophylaxis is cheaper than mosquito reduction. But if this be true for rural areas it is not so for crowded ones.

Malaria Prevention in Sierra Leone

Sierra Leone, which well earned the sobriquet, the "white man's grave," is rapidly losing its reputation. Since the discovery that malaria is due to mosquito bites that scourge has considerably abated. Both Europeans and natives have taken the truth to heart and now take precautions against malaria and other tropical diseases, which were formerly undreamt of. The inhabitants of Freetown (which comprises about one-third of the population) view mosquitoes as bad animals like snakes. The housewife regards the health officer as a friend and does her best to keep her "compound" free from stagnant water. In 1907 the deaths in Freetown from malaria numbered only 202 and last year they dropped to 150. To stimulate the native chiefs to take an interest in sanitation the government offers the prize of a handsome sword to the two chiefs in each district which show the greatest improvement in sanitation. This has proved most effective.

Accident or Disease?

The Workmen's Compensation Act has caused many difficulties in deciding whether the disability of a workman is due to accident or disease. The following case is a new illustration: In 1907 a carpenter was awarded $5 a week compensation from his employer because of an injury to his left arm which was supposed to have preduced dislocation of the ulnar nerve. About a year after the accident similar symptoms appeared in the right arm, and it was discovered that the case was really an example of syringomyelia. As medical opinion was given that the disease had nothing to do with the accident the employer applied to the court for an order to stop the payments. A physician at the hospital in which the patient was treated gave evidence in support of the application, but the resident medical officer of the same institution gave evidence that cases of syringomyelia due to injury had been recorded. In view of the difference of medical opinion the judge would not interfere with the award.

Health Visitors

A remarkable development in sanitary administration in recent years has been the appointment of women as sanitary inspectors and still more recently as "health visitors." Health visitors originated in the voluntary efforts of societies of philanthropic women to improve the sanitary condition of the poor by visiting their houses and instructing them in personal and domestic sanitation. The government has now decided to appoint paid health visitors and has issued regulations on the subject. A woman may qualify herself as a health visitor in five different ways, (1) as a qualified medical practitioner, (2) as a trained nurse, (3) as a certified midwife, (4) by undergoing a course of instruction in a hospital and holding in addition the certificate of certain bodies such as the Royal Sanitary Institute, or (5) by holding some post under a sanitary authority in which she has discharged duties likely to qualify her for the post of health visitor. Health visitors must submit their books when required to do so to the sanitary authority or health officer. The salary will be $500 per annum.

Health of the Navy

The reports on the health of the navy in 1908, which have just been issued, show continued improvement. Not only are the case, invaliding, and death rates lower than the average for the last five years, but the average loss of service per capita has dropped from 11.28 to 10.36 days. The total force was 109,210 and the total number of cases of injury and disease 75,608, which gives a rate of 692 per 1,000, being a decrease of 53 as compared with the average of the preceding five years. The conditions of work in the engine-rooms and stokeholds are the subject of an interesting report by Staff-Surgeon Rees. In regard to heat stroke, he finds that the negro not only has an advantage over the white man in the sun but also in the stokehold. In the sun the lesser diathermacy of his dark skin is an advantage; in the stokehold his skin radiates heat better than the white man's. It is curious that workers in the bunkers are not more liable to heat stroke than those engaged in firing the furnaces, for the bunkers are often much hotter than the stokeholds, while the air in them is often motionless. The explanation appears to be that the stoker working in the bunkers is at once covered with a layer of fine coal dust, which radiates heat much faster than the uncovered body. The best treatment of heat stroke is found to be iced baths.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 29, 1909.

Preserved Foods

At the annual session of the German Public Health Association (*Deutsches Verein für öffentliche Gesundheitspflege*), held at Zürich early in September, Professor Schottelius gave an address on "Preserved Foods as Popular Diet." While fully recognizing the value of preserved foods in cases in which suitable fresh nutriment cannot be procured or only with great difficulty, he laid great emphasis on the fact that fresh food is more wholesome and more nutritious. In the process of artificial preservation changes occur in the natural composition of the foodstuffs and constituents are lost that are of great importance for the digestion and utilization of the food in the body. In his opinion, preserved foods can be dispensed with in all civilized countries with a temperate climate, as at all seasons a sufficient supply of fresh and well keeping foods is available at low prices. Foods preserved in tins are not to be recommended for general consumption, as there is no sufficient security that they will always meet the demands of hygienic safety, especially as there is nothing to show when the goods were put up.

Night Prices of Druggists

Some time ago permission was given to pharmacists by the Department of Education to add 50 per cent. to the price of medicine delivered at night. At the meeting the German Pharmaceutical Association (*Apotheker-Verein*) held a week ago, it was proposed that this rule should be effective from 9 o'clock in the evening to 7 in the morning, instead of, as hitherto, till 6 a. m. In this way the pharmacist will be still further protected against disturbance of his night's rest. Besides this, an increase in the price of medicines corresponding to the cost of labor is demanded, as the prices heretofore in vogue are not sufficient to meet the demands of the steadily increasing cost of living.

Treatment of Hydrophobia

From a report of the Ministry of Education (*Kultusministerium*) it appears that in 1908 in Prussia 295 persons were injured by animals either rabid or suspected of rabies. Of these persons 279 submitted to the Pasteur treatment. (There is a Pasteur institute in Breslau and one in Berlin.) Of the 279 who were inoculated 2 died and of 16 who were not treated 1 died. In 1907, of 382 inoculated, 2 died; in 1906, 4 out of 342; 1905, 3 out of 322; 1904, 5 out of 330; 1903, 4 out of 281. If only those who were bitten by an animal known to be rabid are considered, 2 of 190 inoculated died in 1908, 2 of 266 in 1907, and 4 out of 236 in 1906.

Birth-rate of Various Nationalities

In an article awarded the prize and published by the Bavarian national statistical bureau on the fertility of different civilized countries, the following figures show a steady decrease in the fertility of married women during the three decades ending in 1905, and also for most countries a decrease in the number of illegitimate births. Among 1,000 married women of the ages from 15 to 50 there occurred of legitimate births:

	1876-1885	1886-1895	1896-1905
In the German Empire..........	268	258	243
In Prussia	273	265	250
In Bavaria	276	263	259
In Saxony	267	250	216
In Würtemberg	288	259	262
In Baden	266	248	251
In Austria	246	250	...
In Hungary	234	224	...
In Italy	248	249	232
In Switzerland	239	230	...
In France	167	150	134
In England and Wales..........	250	229	203
In Scotland	271	255	235
In Ireland	250	245	254
In Belgium	264	236	214
In the Netherlands............	293	286	272
In Denmark	244	235	217
In Sweden	240	231	...
In Norway	262	259	...
In Portugal	...	235	...
In Finland	259	246	...
In Servia	...	237	...

The low birth-rate of France is remarkable, and in the last decade that of England and Wales has shown the nearest approach to it. The low figure for Belgium is in striking contrast to that of the neighboring kingdom of the Netherlands, where for the three decades the maximum of fertility among married women has been observed. In the German empire the legitimate fertility has been most reduced in Saxony, while, on the other hand, in regard to illegitimate births, Saxony has held the first place among the countries named, being passed by Hungary only in the decade 1886-95. If these countries are arranged according to the illegitimate births registered during the last decade (for every 1,000 unmarried women from 15 to 50 years) the order will be shown by the following table:

	1876-1885	1886-1895	1896-1905
In the Kingdom of Saxony.........	47	44	41
In the Kingdom of Bavaria........	42	39	37
In the German Empire.............	28	27	26
In Würtemberg	29	27	25
In Denmark	26	24	23
In Prussia	25	24	22
In Baden	22	20	20
In Italy	24	24	19
In France	16	17	18
In Belgium	19	17	17

The Cholera Situation

Cholera in Holland is apparently extinguished. In Russia it has been greatly reduced, but is still present. According to the latest available official report, 858 persons were attacked in the week from July 5 to 11, of whom 384 died. Of these 493 were attacked and 229 died in St. Petersburg and its suburbs. That there is a certain danger for us is shown by the fact that a few days ago cholera appeared in a small place in East Prussia in a raftsman and his wife lately returned from Russia. The raftsman died but the wife is convalescing. Naturally the necessary preventive measures have been taken by the Prussian authorities. The change that has taken place in public sentiment in regard to cholera is shown by this circumstance. Twenty years ago these two cases would have created a panic, not only in Prussia but in the whole population of Germany, while now the report of such an attack of cholera is received with the same equanimity as if the cases were cases of typhoid or other infectious disease.

Painless Tooth Extraction

One of our dentists has recently learned that he cannot with impunity advertise to extract teeth without pain, as dentists are accustomed to advertise in the newspapers and on the billboards. He was convicted of an offense against the law regarding improper competition. The plea of the convicted man on appeal that it had not been shown that his patients felt any pain on extraction of teeth was rejected on the ground that, according to the opinion of experts, it was not always possible to guarantee a painless extraction of teeth.

Orthopedic Instruction in Public Schools

For the prevention of spinal curvature orthopedic instruction is to be introduced into the Berlin public schools for such children as show an improper carriage. If the trouble is more advanced the children must be transferred to an orthopedic institute. A commission composed of teachers and physicians is to determine the necessary means.

Distraining of a Patient by a Physician

In the last few days the distraining of a patient by a physician has become a cause célèbre. Both the public and the daily press have busied themselves with the affair. A very well dressed Russian lady entered the office of the well known ear specialist privat docent Dr. Jansen, and at the end of the consultation, in place of the usual fee of $5.00 (20 marks), expressed the wish to pay temporarily only $1.50 (6 marks), because, as she claimed, she had no larger sum with her. The doctor, irritated on account of previous unfortunate experiences, seized the valuable ear-trumpet of the patient, locked it in a closet and declared that she should recover it only on payment of the remainder of the fee. The public has become greatly excited at this alleged inhumanity of the doctor. Dr. Jansen has stated in an interview that he has been cheated out of about $12,000 (50,000 marks) by Russian patients. It has repeatedly happened to him that patients have acted as did the woman referred to; they have paid less than the usual fee as an installment and have disappeared, never to be seen again. It is easy to see that the doctor wished to make an example to guard himself against further imposition. It may be admitted that he could have chosen a more appropriate object to distrain but that is not essential. It may be assumed as very probable that this patient, instructed by her compatriots, had intended to plunder the doctors, for it is not to be supposed that a lady would go on the street in a foreign city with the small sum of 6 marks and further that the usual fee of a specialist should be unknown to her. While the whole affair, with its publicity, may be unpleasant to the doctor, it will have the desirable result for him that Russian ladies who visit his office in future will provide themselves with the necessary fee.

Occurrence of Epidemic Cerebrospinal Meningitis in Prussia in 1908

In 1908, 1,284 cases of epidemic cerebrospinal meningitis were reported as opposed to 2,591 in the previous year. The largest number occurred in the Rhine province (459), next in Westphalia (323), and in Silesia (177). The largest number occurred in spring (609), than in winter (353). Of those attacked in 1908, 738 (57.6 per cent.) were males, 544 (42.4 per cent.) females, 973 (76 per cent.) were children from one to fifteen years, and the mortality was 713 (56.2 per cent.). The mortality has steadily diminished since 1904, a fact which is attributed by the official report to the increased use of serum therapy. The highest per cent. died in the first week after the attack.

Severe Diabetes After Injury to the Head

Prof. v. Noorden has furnished to the imperial insurance office an interesting report on the etiologic connection between an injury and a severe diabetes mellitus which ran its course to a fatal termination in about ten months. A laborer received a severe blow on the head from a heavy piece of iron which was followed by a nosebleed, giddiness and temporary confusion. About three months after the accident a severe diabetes began which ran a very rapid and fatal course. The occurrence of nosebleed indicates, according to v. Noorden, an injury to the bones of the base of the skull. While the trauma was not great, concussions of the brain without anatomic lesion are, however, the most frequent causes for the origin of traumatic diabetes. In consideration of the fact that he has never seen a slowly developing and latent diabetes suddenly develop in an otherwise vigorous man to an especially severe diabetes, v. Noorden comes to the conclusion that the diabetes was produced by the accident. The imperial insurance office has therefore awarded to the survivors of the unforunate man the required income.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Oct. 1, 1909.

A Delicate Problem of Ethics Before the Society of Legal Medicine

During one of the last sessions of the Society of Legal Medicine (*Société de médecine légale*) Dr. Siredey, physician of the Hospitals of Paris, placed the following case before the society and asked its advice. A young physician had observed, within a very short period of time, two cases of poisoning of therapeutic origin, due to a single colleague, who, being very imperfectly acquainted with quantitative dosing, had prescribed 40 drops of tincture of digitalis for an infant of 4 months and 40 gm. (30 scruples) of syrup of narcein (one of the alkaloids of opium) for another of 7 months. In both cases death took place within twenty-four hours. It appeared that this physician ordinarily gave excessive doses to children and that the pharmacists of the quarter, for fear of accidents, generally replaced the drugs called for in the prescriptions by other anodynes. The physician in question had been warned of the results of his prescriptions and had replied that he knew what he was about and needed no advice.

What ought to be the conduct of the physician who had discovered these cases of poisoning? Did not his silence run the risk of making him an accomplice? Dr. Siredey did not wish to advise his young colleague to become an informer but he asked if the physician whose official duty it was to record deaths (*médecin de l'état civil*) should not be notified. It might also be asked whether, to prevent the recurrence of such accidents, the question should not be placed before the "family council" (*conseil de famille*) of the medical society of the *arrondissement* where the incidents occurred. This interesting case gave rise to very warm debates. According to Dr. Balthazard, professor *agrégé* at the Paris medical school (*faculté de médecine de Paris*) the physician who observed the poisoning ought to tell the family that the child was poisoned. If the fault had been committed by a charlatan, one would not hesitate to denounce him; and because a colleague is in question one has not the right to keep silence. Dr. Chassevant, another *agrégé* of the Paris medical school, thought that the physician who observed the mistake ought not to incite the family to prosecute his colleague, but should warn the *médecin de l'état civil* under sealed cover. This was the course proposed by Siredey and the president of the society and approved of by Dr. Granjux, who considered denunciation of the physician not only blamable itself, but also dangerous; for if the physician who caused the poisoning was acquitted by the courts, could he not then turn on his accuser and prosecute him in his turn? A third opinion recommended complete silence. Dr. Descouts believed that the physician who observed the poisoning ought not to warn the public physician, even indirectly, for according to law it is the duty of the latter to ascertain the cause of the death. He may, for example, demand that the prescriptions be furnished him, and thus he will be able to observe that excessive doses have been prescribed.

An interesting point to which Dr. Chassevant drew attention is the complicity on the part of the pharmacist in such cases. The latter is culpable in habitually replacing the dangerous prescription by anodynes which may have led the physician to persevere in his course by causing him to believe that what he was prescribing was not toxic. The duty of the pharmacist is to report to the physician his slips of the pen. Unfortunately, too many pharmacists turn the filling of prescriptions over to apprentices who are not competent to appreciate when a dose is excessive. Dr. Briand cited a case which well shows the unfortunate consequences which may result from the precaution taken by certain pharmacists of diminishing the prescribed dose. A patient was taking arsenic in pills. The pharmacist, finding the dose too strong, reduced it just in proportion as the physician increased it. One day a new apprentice filled the prescription according to order and the patient was poisoned.

Have Physicians the Right of Concerting to Refuse Their Care to a Patient?

In one of my preceding letters (THE JOURNAL, Jan. 16, 1909, lii, 223) I mentioned an interesting decision of the civil court of Châteauroux, to the effect that physicians had the right to refuse their attentions except when legally ordered and that such refusal gave no ground for an action for damages. But another question was also raised in this case—the physician's right to warn his colleagues that the patient did not pay his fees. The case was appealed, and the court of Bourges has just condemned Dr. Babon to pay $100 (500 francs) damages, on the ground that in warning his colleagues, Dr. Babon had performed an act of vengeance and had done a serious injury to his former patient. According to this decision, each physician may refuse his own services to any patient, but he cannot concert with his colleagues for the same purpose.

Sewage Disposal

Since the hygienists have definitely condemned the draining of sewage into running streams, the city of Paris faces an exceedingly complex problem. At great expense in the western suburbs, sewage fields have been created, where the ground, being particularly permeable, allowed the absorption of large quantities of liquid; but still the ground is to-day saturated to such a degree that leguminous vegetables grown on these fields have such a peculiar odor that they are not salable in the markets. It is even demanded that these products should bear a special label, in order that buyers may recognize them. The market-gardeners of the suburb naturally do not favor an increase of the sewage fields. Moreover, this system is now insufficient, not only because of the relatively rapid saturation of the ground, but still more because of the incessant development of the population of Paris. A few years ago, when a third great receptacle for sewage was opened, the administration required that not a drop of refuse water should be thrown into the Seine any more. Now the daily total of the sewage from public and private sources amounts to 206,032,180 gallons, (780,000 cubic meters), and the various fields which receive the sewage absorb daily only about 145,272,050 gallons (550,000 cubic meters); there remains for each daily period of twenty-four hours 60,760,130 gallons (230,000 cubic meters) of sewage draining into the Seine. This situation is evidently intolerable, apart from the fact that the dwellers on the river banks are able to obtain large indemnities for the injury to their interests. The city of Paris, then, is compelled to put a stop to this state of affairs as early as possible. A sum of $3,000,000 (15,000,000 francs) has been set apart for this purpose, but the method to be employed has not yet been selected.

Measures Against Cholera

In accordance with instructions from the government, samples of waters of all the canals and rivers crossing the French frontiers on the north and northeast have been taken and submitted for bacteriologic analysis to the Pasteur Institute of Paris. This analysis has shown that there is no trace of the cholera vibrio in the waters examined. Although the sanitary situation along the frontiers is much more reassuring, the surveillance mentioned in my previous letter (THE JOURNAL, Oct. 2, 1909, liii, 1111) continues to be exercised throughout the north and northeast of France.

The Hygiene of Dwellings

The National Congress on Sanitation and Salubrity of Dwellings, which will be held next month in Paris, has an exceedingly broad program, the subjects being divided into three classes, as follows:

1. General: inquiry into the application of the law of 1902 for the protection of public health; modifications of this law; modifications in sanitary regulations; free spaces in cities.
2. Special: heating and ventilation of buildings; the education of the people in regard to the hygiene of the dwellings; sanitation of buildings occupied by working people who carry on their trades at home.
3. Military: installation of spray baths in barracks; installation of latrines in barracks, encampments and cantonments.

The organizing committee of the congress has addressed to a certain number of medical societies (*syndicats médicaux*) a series of questions in regard to the results of the law of 1902 in respect to the healthfulness of dwellings, unhealthful buildings and the sanitary records (*casiers sanitaires*). These last comprise records of hygienic conditions of each house, the deaths therein by transmissible diseases, disinfections carried out, dates and causes, etc. In Paris this service of the sanitary records has been in operation since 1894; it shows that certain houses constitute veritable hotbeds of tuberculous infection. There are, in fact, 820 houses which, out of a population of 106,300 tenants, have given, in ten years, 11,500 deaths from tuberculosis, more than 14 deaths per house. Unfortunately, the precise information contained in the sanitary records has had, up to the present, no particular results, for these notes are kept secret, in order not to damage the proprietors. The Congress of Tuberculosis, held in Paris in 1905, passed a resolution asking that the public authorities be given the right and the means of condemning all buildings dangerous for the health of the inhabitants, but this resolution has, up to the present, had no legislative sanction. Moreover, there may be some question whether the destruction of unhealthful buildings would in itself insure the hygiene of dwellings, for the building license, which in other countries, in England especially, is burdened with many restrictions in the public interests, is with us a mere formality, so that the buildings which replace the unhealthful ones destroyed may be just as defective. All our legislation on this point really needs thorough revision.

Sectarian Spirit and Medicine

There exists in France, in addition to the colleges and schools (*Facultés et Ecoles*) of medicine which depend on the government, an establishment which is independent of state control, that is the free or catholic school of medicine and pharmacy (*Faculté libre ou catholique de médecine et de pharmacie*) of Lille, whose pupils, however, pass their examinations before a special board determined by the law and receive a diploma from the government, for no one can practice medicine in France unless he is furnished with a diploma of doctor of medicine, given by the French government. Recently the administrative board of the hospitals of Dunkerque, a city in the same department as Lille, a physician decided to open to competition two new posts for medical men, but with the proviso that no candidate would be accepted except a graduate of the Catholic school of Lille. The medical society (*syndicat médical*) of Dunkerque, justly indignant, passed a resolution protesting against this ruling and demanding that the competition be thrown open to every French physician, on the ground that the diploma given by the French government should carry the right of competing on equal terms for public places and functions.

"The Practitioner's Sundays"

Under the title of "The Practitioner's Sundays" (*Dimanches du praticien*) some physicians have organized in Paris a series of lectures intended to keep practitioners informed in regard to scientific progress in all the branches of medicine. They will be held on Sunday, the only day on which many physicians are at liberty. Because of the lively interest felt in all questions in regard to radium and radiotheraphy, the first lectures will be on this subject. M. Matou, assistant at the Museum of Natural History, will speak on radiations and radioactivity. The following Sunday, Dr. Dominici will talk on the therapeutic application of radium.

The Physicians' "Salon"

A physician's artistic society, called L'Esculape, has just been founded. It has organized for next November an exhibition of works of art by physicians (painting, sculpture, engraving and decorative arts). This society, under the patronage of Drs. Gariel, Gilbert, Marcel Labbé, Richelot, Widal, and others, professors and *agrégés* of the Paris medical school, intends also to give literary, dramatic and musical performances.

Correspondence

Warning Against Impostor

To the Editor:—Kindly warn the profession against a dirty, ragged individual who at present is calling on physicians in Brooklyn, soliciting money to get a meal or two with.

The man is about 5 feet 8 inches tall, with light hair and slight cockney accent. He claims to know the physician's relative in England. He also says that he is going to work his way home on an Atlantic transport liner, but has no money.

He has called on two others besides myself in the past few days. I discovered the fraud by casually mentioning my experience to another physician, who immediately described the beggar. The man will probably try to work other cities.

H. W. Boice, Brooklyn, N. Y.

X-Ray Examination.—The first and greatest value of the *x*-ray examination lies in the fact that it gives information regarding conditions existing in the sick or injured individual, which, in some instances, could not be obtained in any other way, or that it amplifies or confirms evidence obtained by the ordinary means of physical examination.—G. H. Stover, in *Denver Medical Times and Utah Medical Journal.*

Pharmacology

BYE CANCER CURE

Another Cruel Fraud Put Out of Business by the Postal Authorities

One of the most impudent quacks in the "cancer cure" business—B. F. Bye of Indianapolis—has just been officially denied the use of the United States mails. In the "Great American Fraud" the Bye "cancer curers" were shown up and the "piety" of Bye senior, who "founded a little church in Indianapolis with the money extracted from his dupes," was commented on. A few years ago the elder Bye ran a cancer cure fake known as the "Dr. D. M. Bye Combination Oil Cure Company" in Indianapolis, with his son-in-law, L. T. Leach, as manager. At the same time, one of the younger Byes—B. F. Bye—was operating a similar and rival concern in the same city. To quote from the "Great American Fraud":

> "Across the street from the Dr. D. M. Bye offices is the 'down-town office and laboratory' of Dr. B. F. Bye. In the circulars this is pictured as a large and commodious brick building, standing far back in an imposing shaded yard. The picture is purely imaginary. So is that of the doctor's 'Sanatorium' in the same pamphlet. The B. F. Bye outfit is ensconced in a shabby wooden house close to the street, and the 'office and laboratory' are little more imposing inside than outside. The younger Bye makes preposterous claims of 82 per cent. of 'complete recoveries.' . . . His treatment wouldn't remove a wart or cure a mosquito bite."
>
> "Dr. B. F. Bye's correspondence is replete with unconscious humor; *vide* this sample from his 'hurry-up' form-letter: 'When I pause and consider the amount of quackery and humbuggery practiced all over the country, it is not difficult to understand why the afflicted hesitate to accept new treatment, no matter how logical it may be.'
>
> "He belongs to most of the fake medical organizations in the country, whose diplomas (purchased) he proudly displays on his walls."

That useful and overworked department of the postoffice that investigates frauds finally notified Dr. B. F. Bye to show cause why a fraud order should not be issued against him and his "cancer cure" outfit. The facts in the case, as submitted to the Postmaster General by R. P. Goodwin, assistant attorney general, are in part as follows:

"Dr. Bye is engaged in treating persons, afflicted with cancer, through the mails. He has succeeded to the business of his father, who for a number of years was engaged in a similar practice at Indianapolis, Indiana. He is also a brother-in-law of Dr. L. T. Leach,[1] who conducts a similar business from Indianapolis and against whom this office has recommended the issuance of a fraud order. While Dr. Bye advertises to have a sanitarium at Indianapolis where he treats personally patients who come there, the fact is he has no sanitarium of his own and such few persons as do go to Indianapolis for sanitarium treatment he locates in boarding houses and such places.

"On receipt of an inquiry about his treatment, it is Dr. Bye's practice to send the correspondent a circular letter, a question blank, a sheet of testimonials and a booklet bearing the following title:

Cancer, Its Etiology, Pathology and Treatment by Soothing Oils, by Benjamin F. Bye, M.D., Fellow of the American Association of Physicians and Surgeons; Member Indiana Association Physicians and Surgeons; Fellow of the Indianapolis Academy of Medicine; Member of the Incorporated Society of Science, Letters and Art of London, England; Physician to St. Luke's Hospital; Surgeon Hillsboro R. R.; Chief Surgeon Indiana 1st Regiment U. R. K. P.; Examiner of Northwestern Life Insurance Co., Etc., Etc., Etc. Office and Laboratory, Indianapolis, Ind.

MEMBERSHIP IN FAKE ORGANIZATIONS

"The inspector endeavored to ascertain the character of the above associations and societies, and from Dr. George H. Simmons, editor of The Journal of the American Medical Association, found that the 'American Association of Physicians and Surgeons' was in existence several years ago and that its business was in selling of diplomas to physicians and that it was made up of men not recognized by the medical profession as physicians of standing; that the 'Society of Science, Letters and Art of London, England,' was a 'fake diploma factory conducted by a man named Sturman,'[2] and that the same description was applicable to St. Luke's Hospital,[3] Niles, Michigan. As to the Indiana Association of Physicians and Surgeons and the Indianapolis Academy of Medicine, Dr. J. N. Hurty, secretary of the State Board of Health of Indiana, stated that he was unable to find any information concerning either of these societies. Dr. Bye admitted to the inspector that he has not been for some time chief surgeon to the Indiana First Regiment, U. R. K. P., or an examiner for the N. W. Life Insurance Company. It is thus seen that the pretense that Dr. Bye is a man who stands high in his profession and who is connected with recognized medical institutions of standing is false. Dr. Bye is a graduate of the American Medical School[4] of Indianapolis, 1896, and claims to have studied in the Kansas City Homeopathic School. He has never been in private practice, and his entire medical experience has been gained in this mail order cancer cure business.

---

[1] The details of the government's action against Leach and his fake will appear in an early issue of The Journal.—Ed.

CLAIMS MADE

"The representations contained in the circular letter and the booklet are intended and calculated to lead the correspondent to believe that Dr. Bye has discovered a combination of vegetable oils which is most efficacious in the treatment of cancer and that it will cure practically every case. For this treatment $25.00 is asked. Some of the representations made are quoted below:

> A local treatment and the correct indicated remedy exhibited internally is the only rational one, and to be sure, safe and speedy, the local treatment must destroy the embryonic cells; also the foundation bed or "Stroma," and at the same time preserve the integrity of the surrounding healthy tissues. The combination of vegetable oils, where applied to these malignant growths, has accomplished what is so ardently desired.
>
> The oil soon has the growth under its influence, and the disease is soon absorbed, causing a radical cure without pain. In case the diseased parts have already broken down and we have an open sore, the wound will slough in a short time, then it will heal nicely.
>
> . . . we have found that where the patient will follow our instructions closely a rapid cure is the result.
>
> Don't be misled by the claims of irresponsible people as to their ability to cure cancer by the injection of a specific serum or other substances. . . . We have discovered a combination of oils, which in their effect upon the diseased tissues, approaches the miraculous. It is the only successful remedy known to medical science and has the highest indorsement from the medical profession, as well as from ministers and thousands who have been cured. . . . The Oils are soothing and balmy, safe and sure, and cure without disfigurement.
>
> The Combination Oil Cure does cure cancers and tumors to stay cured.

"The correspondent is also led to believe that Dr. Bye can properly diagnose the malady with which he is afflicted from the question blank.

"If the correspondent fails to purchase the medicines after this first solicitation it is the practice of Dr. Bye to write him another letter in which he states that 'from the information I have received I believe that I can effect a cure in this particular case.' In this letter the price of the treatment is reduced to $12.50; and if the treatment is not purchased pursuant to this solicitation, another letter is mailed the prospective patient in which he is asked to purchase a trial treatment which will last him several weeks for $3.00.

THE "CURE" ANALYZED

"The medicines were analyzed by chemists of the Department of Agriculture, and were found to amount to cotton seed oil and some ordinary tonics."

After giving the details of the analysis the government chemists make the following statement regarding the value of the "cure":

> "Analysis of the above treatment shows that it does not contain a single item which is considered of any special service for the cure or successful treatment of cancer, neither is the entire combination such as to warrant any representation to the effect that it is a cure for cancer."

As to the truthfulness of Bye's claim that he produces 82 per cent. of complete recoveries, the following is enlightening:

THE PERCENTAGE OF "CURES"

"The inspector procured from the post-office records the names and addresses of some twenty persons who have taken Dr. Bye's treatment and corresponded with the postmasters at the post-offices where these parties were located, with regard thereto. This correspondence shows that but one of these patients claims to have been cured, and in this case it develops that a surgeon had removed the growth before the Dr. Bye treatment was undertaken, and this surgeon reports that the growth removed was not cancerous."

In summing up, the assistant attorney-general makes the following statement:

"According to the evidence submitted the medical profession knows of no drug or combination of drugs which can be relied upon to cure cancer. That Dr. Bye has not succeeded where the profession has failed and that he is not honestly endeavoring to cure patients, but that his pretensions to have discovered a cure for this disease are false and fraudulent and asserted merely to deceive and defraud suffering humanity, is revealed by the analysis of his medicines and the finding that they are merely cotton seed oil and some ordinary tonics.

"I find that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, in violation of Sections 3929 and 4041, of the Revised Statutes, as amended, and therefore recommend that a fraud order be issued against the above named parties."

The order was issued.

MARMOLA

An Obesity "Cure" of the "Prescription Fake" Variety

To the Editor:—Can you give me any information regarding the composition of "Marmola," a remedy used to reduce flesh?

ROBERT S. MCCOMBS, M.D., Philadelphia.

COMMENT: Marmola belongs to a class of nostrums that has become very common since the passage of the national Food and Drugs Act and which descriptively may be called "prescription fakes." By this we mean that the "patent medicine" is advertised, not as such, but as an apparently innocent ingredient in a "prescription" which the reader is urged to have "filled" at the nearest drug store. Many of these advertisements are published in the form of reading matter, giving no indication of their real character. For example: we read in the *New York World* a short article by "Footlights," a supposititious theatrical press agent, who describes how a certain theatrical manager was able to reduce his "over-weight chorus." He did not "starve them into line, nor worry them verbally into shadows. . . . He simply hung up a new rule in the dressing-rooms, to the effect that every lady less than five feet seven who weighed in excess of 150 pounds must take a spoonful after each meal and at bedtime, of the following: One-half ounce Marmola, one-half ounce fluidextract Cascara Aromatic, and three and one-half ounces of Peppermint Water."

This is merely an example of the devious ways in which "patent medicine" vendors, aided and abetted by many newspapers, attempt to humbug the public. The Marmola Company has used the same methods of advertising its products in Great Britain, except that in the place of cascara and peppermint water, we find the prescription reads:

> "One ounce of fluidextract of Glycyrrhiza, B.P., one-half ounce of Marmola, one ounce of pure glycerin, B.P., and three and one-half ounces of peppermint water."

More recently the concern has been varying its methods by advertising Marmola also in tablet form, giving the address of the company and the price of the preparation. The composition of Marmola was discussed in an article on "Commercial Thyroid Preparations" by Drs. Hunt and Seidell in THE JOURNAL, Oct. 24, 1908. It was there shown that the nostrum depended for its action on thyroid extract. Since that time the *British Medical Journal* has also analyzed the product. The results of this examination "showed the presence of (1) a large proportion of a powdered seaweed agreeing well in characters with the powder of *Fucus vesiculosus*, its identity being further indicated by the composition of the ash; (2) a substance of proteid nature, agreeing well in characters with the powder of dried thyroid gland, its identity being further indicated by the presence of iodin in organic combination; (3) phenolphthalein; (4) sodium chlorid (common salt); and (5) extractive." These ingredients, so far as could be determined, were present approximately in the following quantities, to each dose:

---

[2] See THE JOURNAL, May 29, 1909, p. 1773, for a more extended exposé of this fake.—ED.

[3] Also exposed in THE JOURNAL, June 24, 1899; Oct. 21, 1899; Nov. 16, 1901; May 23, 1903, and June 6, 1903.—ED.

[4] Now extinct.—ED.

Dried thyroid gland	1.4 gr.
Phenolphthalein	0.4 gr.
Sodium chlorid	0.7 gr.
Powdered *Fucus vesiculosus* (bladderwrack)	5.0 gr.
Extractive	2.5 gr.
Oil of peppermint	trace

The danger of the indiscriminate use by the laity of such potent drugs as thyroid extract is evident, and yet we read: "A safer way of reducing fat cannot be imagined than by the use of this pure Marmola prescription."

Purgen Again

To the Editor:—Those who prescribe "Purgen" may be interested in knowing how its popularity is established in Germany. I am sending with this letter the tissue paper cover of a straw such as is furnished with cold drinks in hotels and restaurants. Printed on the tissue paper is the legend:

PURGEN
DAS IDEALE LAXATIVUM
FRAGEN SIE IHREN ARZT!

How many take the trouble to "ask a doctor" is, of course, a question. As these covers are made in Paris, the exploitation may be even more wide-spread.

George Dock., M.D.

Comment: Purgen, it will be remembered, is one of the numerous proprietary names for phenolphthalein and already has been discussed in The Journal. In Europe advertisements of the preparation are to be seen in the street cars, daily press and even on toilet paper (The Journal, Nov. 2, 1907, p. 1541). In this country it is advertised—directly—only through the medical profession—which is cheaper.

Antidote to Hair Dye Poison

To the Editor:—During the past eighteen months I have seen four cases of poisoning caused by Mrs. Potter's Walnut-Juice Hair Stain, and I wish to offer a suggestion as to the treatment. The parts affected should be covered with gauze, saturated with a solution of sodium hyposulphite (sodium thiosulphate) 1 oz. to 4 oz. of water. This neutralizes the poison on the same principle as it acts when used for "fixing" photographic negatives. The relief from the burning, itching and pain, is almost instantaneous.

Alvin S. Storey, M.D., Cleveland, O.

Comment: The remedy suggested by Dr. Storey will, doubtless, prove of interest to a number of our readers. We have had reported to us no fewer than twenty-one cases of poisoning due to the use of Mrs. Potter's Walnut-Juice Hair Stain. This dye, which, according to published analyses, does not depend for its effect on walnut juice, has recently had its name modified—on the label and container. We see, however, in the daily papers, that the preparation is still advertised as a "Walnut-Juice Hair Stain," and the deception is carried still further by the picture of a woman with a basket on her arm and the legend, "Gathering Walnuts," under it. On the label, however, where direct lying has become illegal, owing to the Pure Food and Drugs Act, it has ceased to be "Walnut-Juice Hair Stain Compound" and has become "Walnut-Tint Hair Stain."

Eade's Gout Pills

To the Editor:—Can you give me any information about "Eade's Gout Pills?" B. S. Denzer, Baltimore.

Answer: This nostrum is made by a British firm, the agents for the United States being Fougera & Co., New York City. The pills are advertised to "Cure Gout, Rheumatism, Rheumatic Gout, Sciatica, Lumbago and all pains in the head, face and limbs." In the report of the Australian Royal Commission on Secret Drugs, Cures and Foods, a qualitative analysis of the nostrum is given as made by Robert Hutchison, M.D., F.R.C.P. According to this, Eade's Pills contain sodium salicylate, guaiacum and aloes.

Miscellany

Treatment of Hookworm Disease.—As many patients can not afford to lose time from work, Dr. C. Wardell Stiles (*Public Health Reports*) advises the devotion of Sunday to the administration of thymol for the expulsion of hookworms. The friends should be warned that the patient is to receive no food containing alcohol, fats or oil, lest absorption of thymol occur. In one case serious thymol poisoning occurred after the patient took a copious drink of milk the day thymol was taken. On Saturday evening a dose of Epsom salts should be given to clear away mucus that surrounds the parasites. The details are as follows:

1. *Position of Patient.*—The patient should be instructed to lie on his right side immediately before taking the drug and to remain in that position for at least half an hour after. The reason for this is that many of these patients have enlarged stomachs, and if they lie on their right side, the drug has the benefit of gravity in passing rapidly from the stomach to the intestine; but if any other position is assumed, the drug may remain in the dilated cardiac portion of the stomach for some hours and result in considerable complaint on the part of the patient and delay of the drug in reaching the worms.

2. *Time of Dosage.*—The time of giving and size of dose should be arranged on one of two plans, depending on existing conditions.

(a) The plan usually followed is: At 6 a. m., one-half of the total dose of thymol; at 8 a. m., one-half of the total dose of thymol; at 10 a. m., Epsom salts (never castor oil).

(b) If the case is an especially severe one, or if the patient has, on the first Sunday's treatment, complained of burning or other effects of thymol, the following plan is adopted: At 6 a. m., one-third of the total dose of thymol; at 7 a. m., one-third of the total dose of thymol; at 8 a. m., one-third of the total dose of thymol (if unpleasant symptoms, as a sensation of severe burning in the stomach, have appeared this third dose should be omitted); at 10 a. m., Epsom salts (never castor oil).

3. *Food.*—No food is allowed until after the 10 o'clock dose of Epsom salts, but the patient is permitted to take a glass or so of water after the thymol, if he desires.

4. *Thymol.*—Finely powdered thymol in capsules, preferably in 5-grain capsules, should be used. Before being powdered the thymol should consist of colorless translucent crystals.

5. *Age.*—The dose should be adapted to the apparent age and strength of the patient. The following represent the maximum amount to be used during one treatment: Under 5 years old, 7½ grains; from 5 to 9 years, 15 grains; from 10 to 14 years, 30 grains; from 15 to 19 years, 45 grains; from 20 to 59 years, 45 grains; above 60 years old, 30 to 45 grains. Total dose to be divided as indicated in Paragraph 2.

Repetition of Treatment.—The foregoing treatment is repeated once a week, preliminary treatment Saturday evening and thymol on Sunday morning, until the patient is discharged.

Duration of Treatment.—To recognize whether the parasites are all expelled, and therefore to determine when to end the thymol treatment, either of two plans may be adopted, namely:

(a) Microscopic examination: On Saturday morning ten microscopi [illegible] esh stool should be made. If eggs are still [illegible] is repeated; if eggs are not found the thym [illegible] takes about forty to sixty minutes to make this examination of ten slides thoroughly.

(b) Cheese-cloth method: A much easier way of recognizing the completion of the treatment, and for practical results nearly as satisfactory as the microscopic examination, is to instruct the patient to wash all of his stools Sunday, Monday, and Tuesday, through a cheese-cloth and to keep the cheese-cloth moist and bring it to the office on Tuesday. While the fecal material will wash through, the worms will be retained in the cloth. Treatment is continued as long as worms are found in the cheese-cloth.

Other Treatment.—If desired, iron may be administered on the days on which the thymol is not taken. It is a good plan, however, not to give iron during the first week, for it is quite important to convince the patient that the thymol treatment is the one which is really accomplishing the lasting good. If the drug is taken Sunday, the patient is likely to begin to feel some benefit by Wednesday or Thursday; his family is likely to notice it on Thursday or Friday. If iron is given during the first week, the conclusion may perhaps be drawn by the patient that it is really the iron which is causing the improvement, and he may discontinue the thymol. Of the two, the thymol is, of course, the far more important, for it reaches the parasite, while the iron reaches only the patient.

Pellagra in Italy.—In spite of the philanthropic and scientific efforts made against pellagra the disease continues to spread in Italy, although the total number of cases is somewhat smaller than formerly. According to a report by Assistant Surgeon R. A. C. Wollenberg (*Public Health Reports*, July 23, 1909) the number of pellagrins in Italy has diminished from 97,855 in 1879 to 55,029 in 1905, and may be estimated as less than 50,000 at the present time. The total number of deaths has markedly diminished from 3,987 in 1898 to 376 in 1907. In 1902 a law was passed making it illegal to sell or to store for sale any immature, musty or spoiled corn. The law also provided government aid for those affected with the disease and authorized the distribution of food to poor pellagrins and their families. It is difficult to enforce the law fully and it is probable that meal made from defective corn or adulterated with such corn products is still sold to a considerable extent. Sanarelli recommends a municipal milling service to overcome this difficulty and the prohibition of milling of deteriorated maize for any purpose whatsoever. The geographic distribution of pellagra in Italy shows that it is spreading to the southern districts and is well established in central Italy, but during the last twenty years the extent of the disease has lessened considerably in the northern part of Italy. The reason for this better showing in the north is not altogether plain, but is partly attributed to the economic, social, and sanitary improvements that have been effected there in recent years. A hereditary predisposition to the disease has been shown. The investigations of Probizer among school children show the offspring of parents afflicted with pellagra to be quite generally of poor development, both physical and mental. In the treatment of the disease, Ghirardini has recently used atoxyl by injection. He states that it is well tolerated and improves the general nutrition, the psychic disturbances, and the ataxia. Gatti used serum from the recovered pellagrin in the treatment of two cases of typhoid pellagra. A general reaction appeared after one hour, with a rise in temperature. The fever was of short duration, defervescence lasting from one to three days, during which time there was a remission of all acute symptoms.

Hookworm Disease and the Negro.—The sociologic importance of hookworm disease is made prominent in a report by C. W. Stiles (*Public Health Reports*, July 30, 1909), who considers especially the relation of the negro to this disease. The worm has been named *Necator americanus*, which means "American murderer," on account of the great loss of life occasioned by it. The disease is known to exist in Africa and it is possible that it was brought to this country by the negro from his native home. The negro is partially immune, so that the symptoms of the disease are less manifest but investigation has disclosed a number of cases in a mild or latent form in the black race. The worm may enter the human system either with food and drink or through the skin and it is probable that the latter mode of entry is the more common. Unhygienic modes of living, especially when they lead to soil pollution greatly favor infection with this parasite. The negro is more likely to lack, or to fail to avail himself of proper privy facilities than the white and in accordance with this tendency it is found that in the southern states hookworm disease is more common in the negroes than in the whites. This is especially true of country districts, where not only farms, but even schools and churches are unprovided with privies. While the direct effects of the disease are less marked in the negroes than in the whites, yet long-continued infection induces anemia, makes the organism less resistant to disease and favors the occurrence of other infections. "In other words," says Stiles, "hookworm infection has an indirect effect in increasing the death rate from pulmonary tuberculosis." As the tuberculosis death rate is about three times as great in the negro as in the white, it is probable that the lessened direct mortality from hookworm disease is compensated for by the increase of tuberculosis as an indirect effect. Another important direct effect is the reduction of intellectual activity and learning capacity during the school period. Children so affected are apt to study and learn with difficulty; this is marked in negro children. The importance of properly constructed privies provided with means to protect soil from pollution and the feces from the access of flies is strongly urged by Stiles. The valuable influences to be exerted by preachers and teachers are thus summed up: "It lies within the power of preachers and teachers to play a very important rôle in reducing the death rate. They are the persons to whom many people look to set the example. If preachers and teachers themselves permit the yards of churches and schools to be defiled by soil pollution, it need not be thought strange if farmers permit soil pollution to occur around the homes. Further, it should be recalled that every church and every school around which soil pollution is permitted to occur may act as a disease-breeding center from which infection can be spread to the farms and homes. Further, also, not only can preachers and teachers do good by setting an example in preventing soil pollution, but if they will point out to their friends the dangers which this pernicious habit carries with it, they can be very important factors in inducing the public to institute more sanitary customs, and thereby they can be important factors in reducing the death rate."

Sense Culture.—P. W. Goldsbury (*Boston Med. and Surg. Jour.*, July 1, 1909), attempts to prove that nerve organs of the special senses, no less than the other organs and muscles, need for their healthful development adjustment of rest and stimulation, and that, as the brain must be rested somewhat by readjustment of energies within itself, the different sense organs may be refreshed by varying and qualifying forms of stimulation peculiar to themselves. Physical culture seeks to recreate by variations of the expressive or muscular activities. Why, asks Goldsbury, should not variations of stimulation for the avenues of impressions, the special senses, be used for their tonic effect? The eye may be rested after protracted use by merely closing the lid. But further rest may also be obtained by the playing off, so to speak, of one sense against another by diverting activity. For instance, if we stand and watch a circus parade for any length of time our eyes soon become tired by the "sights and features;" but the bursts of music from the bands, by stimulating the ear, relieve and freshen the eye. Musical comedy shows how the tax on the eye by the costumes, colorings and lights is relieved by the interpolation of music and songs. Even the popular concert where foods are served has a physiologic basis. The air, the water, and the mud baths peculiar to the famous health resorts called hot springs have a marvelous recuperative effect on tired minds and bodies. They stimulate the skin by drawing the blood to it; they give it healthful exercise and so rest and refresh the brain and eyes and ears that have been tortured by the incessant strain and noise and ugly sights and incidentally by the strenuous life. As the brain is refreshed by a different line of thought, or as the stomach and intestines may be improved by a readjustment of diet, so the senses may be recreated by a change of stimulus. The tired ear may be refreshed by simple variation in the sound it hears; that is, by being afforded stimulation in new directions.

Exercising the eye by change of focus seems to have a tonic effect. Looking from one object to another not only affords muscular but sensory exercise. A change of form affords a change of stimulus for the retina. Different colors may be said to afford qualitative variations in stimuli. The colors of the spectrum stand for a variation of wave length. Under ordinary conditions, red tires the eye sooner than green or brown. Goldsbury has a box with a series of small boards exhibiting different paint stains, and asks the patient to shuffle these over several times a day. For office workers whose eyes are so much on white paper and black ink, these varied tints of color and the grain of the wood afford a little soothing and diverting eye exercise, and occasionally this is found to relieve the headache of eyestrain.

The strong smelling-bottle when used is like a solar plexus blow; instead of this Goldsbury has a little case of four bottles containing mild selected odors. Occasional sniffs from these in turn result in a light form of gymnastics for the olfactory tract. To exercise this tract is to stimulate its circulation and this helps to relieve congestion in overstimulated adjacent tracts, as of the eye or ear, whether in the brain or outside of it.

As the skin is more or less susceptible to the feeling of all textures and dyes for clothing worn, there is plenty of opportunity for regulations as to changes at stated intervals of both inner and outer garments, shoes and stockings. Consideration should also be taken of the reactionary influence of the color of clothing on the eye. Air, water, and sun baths in all their various modifications are, in a way, subsidiary agencies of skin-stimulations. Taste must be indulged by being encouraged to choose more what it likes and by giving it more time to act. This would call for thorough mastication of food and the avoidance of flooding out the mouth when drinking. All the avenues for impressions in all their ramifications must be studied specifically and individually.

Stokes-Adams Disease and Lesions of the Bundle of His.—Vaquez and Esmein (*Bull. et mém. Soc. méd. d. hôp. de Paris*, December, 1908, No. 36) report several cases of Stokes-Adams disease, two of them with autopsy showing lesions (sclerogummous infiltration and old sclerosis) of the bundle of His.

In discussing these cases, besides pointing out its two types, they deduce some therapeutic conclusions of interest. Out of twenty cases of which they have found sufficient clinical and anatomic reports, syphilis was the certain etiologic factor in seven, and the probable one in a number of others. In the early stages of the disorder they advise therefore a resort, as quickly as possible, to specific medication, whether there is a history of luetic infection or not. By this means we have a chance to multiply the number of cases in which the condition does not progress until incurable sclerosis has occurred. In the same issue of the *Bulletin* and apropos to the communication of MM. Vaquez and Esmein, M. Louis Renon gives the history of a case of the disorder, seen in the first stages, with a syphilitic history dating back ten years. On the suspicion that he might have to do with a specific disease of the bundle of His, Renon treated the patient with antisyphilitic injections. These resulted in great amelioration of the patient's condition, although he can not call it a definite cure. The treatment has perhaps arrested the progress of the disorder and prevented its passing into the later stage characterized by permanent slow pulse, as pointed out by Vaquez and Esmein.

Building of Sanatoriums.—T. S. Carrington (*Journal of the Outdoor Life*, September, 1909) gives some suggestions as to the site and construction of sanatoriums. The sanatorium may do society harm if it places patients in luxurious surroundings and creates a mental state that will unfit them for the life to which they must return. Excellent results have been obtained by institutions providing only the actual necessities of life, and the observance of simplicity and economy in sanatorium construction avoids the danger of ruining the citizen while curing the individual. In selecting a site proximity, accessibility to friends and the former homes of the patients should be regarded as great advantages, but if the institution is to be a large one the climatic factor must be considered. It is well to remember that vastly differing climatic conditions are often found within a radius of a few miles. The southern exposure of a hill or mountain is usually to be preferred, and sites where strong prevailing winds exist during certain seasons of the year should be avoided. Some sort of an administration building should be provided and the lean-tos or cottages grouped about it; or if the institution is very large, separate groups of buildings should have separate local administration apartments in connection by telephone with a central administration building. Unless the climatic conditions necessitate corridors to connect the buildings, they may be omitted. Every effort should be made to give to the patients' quarters the most pleasant outlook possible. The lean-to style of building is at once the most economical and secures the best supply of fresh air, but even with one side of the room entirely open, ventilation must not be neglected or the air may become foul.

The Card Index System for Circularizing.—M. Perrin writes to the *Presse Médicale*, August 14, 1909, to suggest that persons advertising automobiles, sanatoriums, etc., should adopt the international card index form for their advertisements sent to individuals, which can then be readily classified like the card index in the libraries. These interchangeable cards for the international uniform index system are always 125x75 mm. (about 5x3 inches). He gives some examples and urges the great value of this method of advertising which would much facilitate ready reference, instead of the heterogeneous mass of circulars, pamphlets, etc., which now flood the mail and which it is impossible to preserve conveniently, much less to classify for ready reference.

Brain Storm.—At a meeting of the Chester County Medical Society, Dr. Frank Woodbury, secretary of the committee on lunacy in Pennsylvania, defined brain storm as a figure of speech used to express the idea of a sudden attack of mental perturbation. By analogy it graphically illustrates a psychic or mental commotion by calling to the mind of the hearer or reader the associated idea of a familiar physical phenomenon. Analogous terms used by writers in describing the same emotion have been "mental whirlwind," "maniacal explosion," "stormy irregularity of temperament attending maniacal outbursts," and "a hideous whirlpool of emotion." A summary of Dr. Woodbury's definition of "brain storm" is as follows: 1. Brain storm is a phrase familiarly used to describe brief states of mental emotion or perturbation without reference to their cause; it is a popular and not a scientific term. 2. Such attacks may be influenced by atmospheric and climatic conditions to an extent not usually known or suspected. 3. The presumed proximate causes in such cases are only incidental; they only lay the match to the mine which produces the explosion; the real causes lie deeper. Emotional, confusional conditions may occur in apparently normal persons, but are encountered more frequently among the insane. 5. Brain storms, so called, will be observed most frequently in persons who are neurasthenic and in a depressed vital condition; they are frequently epileptic or epileptiform. 6. Brain storms usually indicate pathologic conditions of the body or mind, but they are symptomatic of general conditions and are not of specific significance. Violent outbursts of rage or emotion have medical importance, and when of frequent occurrence should be investigated by a physician skilled in mental disorders.

Osteopathy Is Limited in New York.—We quote the following from an editorial in the *New York Commercial*, Sept. 21, 1909: "Not only the medical fraternity but the public as well will be deeply interested in the latest phase of the controversy over the legal and the medical standing of the osteopaths. One of the leading practitioners of this school in Brooklyn has just been denied by Justice Crane of the supreme court an injunction compelling the New York City authorities to grant him the same privilege of issuing death certificates for burial purposes as is enjoyed by regular graduate and licensed physicians. And the decision appears to be not only the only one that would be made under the circumstances, but also to be logical and eminently fair.

"It will be recalled that some months ago this same osteopath and his associates secured from the New York court of appeals an opinion that sustained them in their claims and contentions—that a licensed osteopath is not only a physician but under the sanitary code is also empowered to issue death certificates—but it plainly, although delicately, intimated that the code ought to be changed so as to make a distinction between the two classes of practitioners. This decision said in part:

" 'Where death is caused by criminal means it usually occurs through external violence or from poison. The osteopath is precluded by the law from practising surgery or administering drugs, presumably for the reason that his education does not qualify him to practice where either drugs or surgery may be necessary. I am therefore not prepared to say that the board of health may not properly require that a certificate of death, which would exclude from the cause thereof either wounds or poison, be made by a physician who is competent to judge such matters. It is sufficient for the disposition of this case to say that the sanitary code now in force draws no such distinction between the two classes of physicians; but I think we should not intimate that the sanitary code may not properly be amended in this respect.' "

"The adroit use of negatives in this ruling is somewhat unique. The board of health understood the suggestion, however, and the change was promptly made—and with propriety, too. For how can a practitioner prohibited by law to practice surgery testify competently as to whether or not an apparently fractured skull is really fractured? Or how can one not permitted to administer drugs make oath that carbolic acid was the cause of a suicide's death?"

Treatment of Pleurisy.—A. Jacobi, in the *Monthly Cyclopedia and Medical Bulletin*, states that dry pleurisy with its excessive pain, demands morphin, never internally, but subcutaneously. Internally it will have no effect such as one wants; subcutaneously, that means locally over the seat of the pain, it will never fail. It will not cure the pleurisy, but will relieve and aid in curing the patient. Cough and sleeplessness caused by pain, must be relieved by an opiate. The physician may kill the patient by not relieving him. The fanatic interdiction of opium in the cases of infants is copied from one text-book into the next by those who treat people at their desks and not at the bedside.

A Longevity Trust.—The Metropolitan Life Insurance Company, in its campaign against tuberculosis, has issued for the instruction of its policy-holders, 3,500,000 pamphlets on the treatment and care of tuberculosis in the home, and proposes to establish a large sanitarium in the northern part of the State of New York, for the treatment of advanced tuberculosis among its policy-holders. The New York *Times*, commenting on this movement, says editorially that the term "life-insurance" never meant the insuring of lives until this year; that the agents of the companies "might easily be transformed into a militant body of health agents," armed with advice in regard to hygienic living for the benefit of the millions of policy-holders; and that "a staff of visiting physicians, specialists in the chief diseases," might be sent to treat policy-holders in each community who could not otherwise command skilled medical services. "By such work," continues the *Times*, "the companies would have fewer death claims to pay. They could promise larger benefits. But this, which has hitherto been a deciding argument in insurance competition, is only incidental to the added promise that the policy-holder's life, which is of quite inestimable value to his family, would be guarded. The competition of the life insurance companies, once started toward the prolongation of their patrons' lives, will not end until not only tuberculosis, but all the diseases that figure largely in the actuarial tables, become the subject of skilled attention. The lives of most men who can afford to employ a doctor are already 'insured.' Ultimately, we presume, those physicians not retained by the companies would be reduced to treating minor ills, or forced quite out of their profession. The organization of preventive medicine has reached startling proportions, but it has failed to keep pace with the progress of medical science. This progress is so rapid that the medical colleges complain that they can not catch up in their equipment. But if the new departure in life-insurance means anything, it means that the companies are beginning to resolve themselves into what they have an inherent right to be—companies of physicians—a longevity trust."

Cottonseed Oil Superior to Olive Oil.—So much emphasis has been placed on the fraudulent adulteration of olive oil by means of cottonseed oil that the impression has become very general that cottonseed oil was not suitable for the human stomach. The manufacturers of cottonseed oil in the south are evidently commencing a propaganda of education. If some of the statements we have seen are correct, cottonseed oil should be able to stand on its own merits as a food and to supplant olive oil to a certain extent. Because of the interest which attaches itself to this question, but without any investigation as to the accuracy of the statements, we abstract the following from an article which was published in *Life and Health* by Dr. O. C. Godsmark: The absolute purity and freedom from disease contamination, which obtain in the production of cottonseed oil, make this oil valuable as a food commodity. It is said to be more readily received and assimilated into the system than peanut butter, corn oil, or even the pure olive oil itself. Professor Moore of Arkansas State University states that of 100 parts of pure cottonseed oil, 93.37 parts are digested; of olive oil, 88.81 parts; of peanut oil, 85.87 parts; of corn oil, 86.47 parts; while of beef suet but 73.66 parts in 100 are digested. The substitution of the pure cottonseed oil in emulsions, in place of cod-liver oil, has been urged, and is even now being done. In the treatment of tuberculosis, when the emulsion is used, 25 out of 100 persons can use cod-liver oil emulsion, 75 out of 100 can take the emulsion when cottonseed oil is used, it being that much more easily assimilated by the weakened digestive organs of the patient. Dr. H. W. Wiley says that one unit of cottonseed oil will furnish over twice as much heat and energy as the same quantity of sugar or starch. When used with salt on bread, it makes a very acceptable substitute for cream and butter, and certainly is free from the diseases we contract from the animal world. Not only is cottonseed oil more easily digested than corn oil, peanut butter and even olive oil, but it also does not ferment in the stomach and bring on that long train of evils that have come from the too abundant use of some of the articles mentioned.

Book Notices

THE PSYCHOLOGY OF DEMENTIA PRÆCOX. By Dr. C. G. Jung, Privat-Docent in Psychiatry, University of Zurich. Authorized Translation with Introduction by Frederick Peterson, M.D., Professor of Psychiatry, Columbia University, New York, and A. A. Brill, Ph.B., M.D., Assistant in Psychiatry, Columbia University, New York. Paper. Pp. 153. Price, $2. New York: The Journal of Nervous and Mental Disease Publishing Co., 1909.

As a term of diagnosis "insanity" has become almost as meaningless as "paralysis," "apoplexy," "chorea" and "water on the brain." Even "mania," "melancholia," "paranoia" and "dementia" are fast losing their scientific significance, if indeed they ever had any. The word "psychosis," borrowed from psychology and applied scientifically, in modern psychiatry, to all states of unwonted mentalization, is coming more and more to stand for a particular class of phenomena, namely, individual psychophysiologic reaction to environment.

In consonance with the newer teachings of psychology it is beginning to be recognized that there are no mental diseases in the old sense, capable of classification as distinct and separate entities, but that there are merely broad and general groups of symptoms and strange mental exhibitions, each group indicating in a gross way the individual's bias or personal idiosyncrasy. Personality is a functional synthesis evolved under the influence of heredity and environment, a fact which explains why each patient has, so to say, his own psychosis or insanity.

In modern psychiatry, therefore, quite a new point of view has been assumed whereby more stress is laid on the cause, course and conclusion of the case than used to be done and far less on the mere strangeness and incongruity of the symptomatic display. Indeed, the symptoms of insanity are now regarded as quite unreliable for the purposes of diagnosis until they and the patient have been subjected to the closest sort of psychoanalysis. It has been more than once demonstrated that there is no more justification for the diagnosis of insanity on the strangeness merely of the patient's thinking and acting than there would be in making such a diagnosis on the strangeness of the thinking and acting of a savage.

So transcendingly important have become the patient's individual heredity and environment in modern psychiatry that these factors must be kept ever foremost in the mind of the examiner during a psychoanalysis. Not for a moment to-day will mere queerness and singularity of thought and action serve as conclusive evidence of mental aberration; only the relationship of the patient's thought and action to the thought and action of his previous state, his family, his neighborhood, race, and nation and all those elements and factors that fall within the sphere of his own heredity and environment, will finally determine whether he is, or is not, insane.

This new point of view of modern psychiatry, which unfortunately has not yet been fully recognized by the courts or the rank and file of the profession, and which will probably not be so recognized for a long time to come because of the almost universal lack of training in psychology and because of the great labor and skill required in the making of a thorough psychologic examination, is being taken by many of the more advanced thinkers. As a method of study it opens up quite a new field. Among the earlier pioneers to enter this field Breuer and Freud deserve great credit for their many exhaustive psychoanalyses and the brilliant light they have shed on the nature and symptoms of hysteria, dreams, and dream states. Recognizing this, Jung, another pioneer, has attempted to explain the general, indefinite form of mental aberration to which Kraepelin has given the name "dementia præcox" and of which he has so admirably described the clinical features, on the basis of individual psychoanalysis. Jung's dominant suggestion, running all through his book, is that a close psychoanalysis of each case of so-called dementia præcox ought to and does enable us to correlate all the clinical manifestations with the known data of the patient's particular personality as it has been elaborated by his known heredity and environment. In other words, dementia præcox is not to be regarded as a disease entity, but merely as a state of mind capable of analysis and explanation on a basis of individual and comparative psychophysiology.

Though "this work is the fruit of three years' experimental labor and clinical observation," Jung modestly disclaims having attempted more than to show how, by certain psychologic investigations, he reached views which he deems "fit for the stimulation of the problems of the individual psychologic basis of dementia præcox in a new and fruitful direction." In this, we think, he has succeeded admirably and with Dr. Peterson, who writes a most illuminating introduction to the book, we agree that Jung shows that just as in normal individuals and in hysteria the complex continues to play its part in dementia præcox, and as it does in dreams, the psychosis tends to actualize the repressed wishes from normal life;" and furthermore, that "the otherwise known absurdities and incomprehensibilities become quite clear," by reason of every case having "its special interests and its own individuality."

There are five chapters in the book. The first is devoted to a semi-historical and critical presentation of the earlier theories of the psychology of dementia præcox. The second is occupied with a study of the emotional complex and its general action on the psyche. "The essential basis of our personality is affectivity. Thought and action are only, as it were, symptoms of affectivity." In Chapter 3 the influence of the emotional complex on association is examined, with abundant illustration. In Chapter 4 an interesting parallel is drawn between dementia præcox and hysteria. "Between hysteria and dementia præcox there is only a resemblance of the psychologic mechanisms but no identity. In dementia præcox these mechanisms reach much deeper, perhaps, because they are complicated by toxic effects." And yet while there is no identity, it is nevertheless true, as Jung affirms, that "the psychologic mechanisms of dreams and hysteria are most closely related to those of dementia præcox. . . . The dreamer finds himself in a new and different world which he has projected out of himself. Let the dreamer walk about and act like one awakened and we have the clinical picture of dementia præcox." The entire fifth chapter, the longest and perhaps the most valuable, is taken up with the analysis of a case of paranoid dementia as a paradigm.

To those who would like to learn the trend of modern psychiatric investigation and to note the valuable contributions of the newer psychology to the solution of the intricate problems of mental disease we would urgently recommend the reading of Jung's work, both for its stimulating effect toward further thought and as an illustration of what a thorough psychologic analysis and diagnosis of a case of mental disease involves or presupposes in the examiner.

The translator and editor are to be highly complimented on the skill with which they have given to the American reader a correct and lucid presentation of one of that class of books usually considered the hardest to comprehend, namely, those devoted to the problems in abnormal psychology.

INFANT FEEDING. By J. S. Fowler, M.D., F.R.C.P., Physician to the Royal Hospital for Sick Children, Edinburgh. Cloth. Pp. 230, with illustrations. Price, $1.50. New York: Oxford University Press, 1909.

This very attractive little flexible-covered manual is a worthy companion to the many compact, simple and extremely lucid guides to infant-feeding that have come to us from time to time from English pediatricians. While in many ways following ideas current in England and the United States, it has a marked individuality and we find different methods giving a greater or less proportional value as a result of Dr. Fowler's own experiences. Thus he devotes ten pages to Budin's method of feeding undiluted sterilized (forty minutes) cow's milk to nearly all infants, and reports results but little less favorable than those of the French author himself. Relatively little is said of sodium citrate, and then it is recommended only to meet certain definite indications, and not as a sort of infant-feeding panacea, to which some of Dr. Fowler's countrymen have exalted it. Dr. Fowler is lukewarm in his attitude toward the percentage system, "a method still largely employed in America," and while he is unstinted in his commendation of the great work done by Rotch, he does not believe that the minute fractional elaboration of that system has any practical value. The book does not, of course, as yet reflect the recent German advances, but is an admirable, clean-cut, sane presentation of this complex subject up to that point.

BACTERIAL FOOD POISONING. By Prof. Dr. A. Dieudonné, Munich. Translated and Edited, with Additions, by Dr. Charles Frederick Bolduan, Bacteriologist, Research Laboratory, Department of Health, City of New York. Cloth. Pp. 128. Price, $1.00. New York: E. B. Treat & Co., 1909.

Dr. Dieudonné maintains the position that most cases of food poisoning are due to the contamination of foods by certain specific bacteria. The *Bacillus proteus* in particular is incriminated; an arraignment not easy to understand in so far as the proteus bacillus is very extensively distributed, while typical cases of food-poisoning are very rare. *Bacillus enteritidis*, *Bacillus paratyphi* and the anaërobic *Bacillus botulinus* are all carefully discussed and their more or less hypothetical rôle in the production of various forms of food-poisoning explained. Ptomain poisoning by autolysis without the intervention of bacteria is not at all considered. Food intoxication by metallic poisons is declared to be much more rare than commonly assumed, but the facts adduced in favor of this view are rather scanty and the argument not altogether convincing.

Too much space is given to the purely bacteriologic aspect of the question, as for instance the cultural characteristics and the morphology of various well-known bacteria; not enough attention is bestowed on the finer details of symptomatology and diagnosis. The rules of prophylaxis are in some instances almost naive, as for instance, "meat showing evidence of putrefaction should not be eaten;" nearly all the other rules of prophylaxis are trite and essentially amount to a plea for cleanliness in the handling, preservation and preparation of foods. Here and there a suggestion is made in regard to serodiagnosis, but no definitely new facts are given; nor does it seem feasible from a clinical standpoint to attempt the serodiagnosis of a series of disorders, apparently of manifold origin, that either run a rapidly fatal course or quickly hasten to spontaneous recovery. The treatment advised is essentially eliminative and symptomatic. All in all, the book is an interesting review of the whole subject of food-poisoning, well classified and complete from the historic and casuistic standpoint; it is a convenient reference work for the bacteriologist and pathologist, but of relatively small clinical value to the practitioner. The translation is very good.

THE THERAPEUTICS OF RADIANT LIGHT AND HEAT AND CONVECTIVE HEAT. By William Benham Snow, M.D., Author of "A Manual on Electro-Static Modes of Application, Therapeutics, Radiography, and Radiotherapy." Cloth. Pp. 119. Price, $2. New York: Scientific Authors' Publishing Co., 349 W. 57th St.

This manual of 110 large octavo pages is devoted to the therapeutic application of the various forms of radiant energy. It is hard to classify some of the books on the therapeutics of radiant energy. They are not entitled to be classed as fiction; neither are they narratives of facts as the unenthusiastic observer sees them. The authors will assume some law of "harmonic vibration" or something of that kind, and then from such premises will by deduction arrive at a system of physical therapeutics. Pathology does not play a very important part in such systems, but they are strong on the influence of various "modalities" on molecules and cells and metabolism. The style usually suggests that in which other systems of therapeutics, most of them of lamented memory, were set forth with their enthusiasm, their innocent superiority to critical analysis, and their unbounded love for panaceas.

The book before us belongs in this class. "In accord with the law of harmonic vibration, it is probable that the tissues attune themselves from a source of mixed vibrations, as of the combined spectral vibrations of radiant light and heat, deriving therefrom by selection the kind of energy which sets up and restores functional activity. . . ."

"These higher frequencies of radiant energy conserve the chemical actions and the more gross and energetic mechanical agencies, as certain electrical modalities, mechanical vibration and exercise conserve the mechanical demands for relieving stasis and infiltration, and also increasing the activity of the grosser functions of the organism."

"From the point of view suggested by the above premises it will be recognized that the study of the application of these vibratory agents to therapeutics suggests the investigation of the principles of adaptation of external vibratory energy to the restoration of the body, properly sustained, to its normal vibration in all its parts, as evidenced by the revival of health with the restoration of functional activities." And there you are—a bit groggy, doubtless, but still conscious. Of course a book which starts off with such metaphysics can not be followed very far by one who keeps his feet on the earth.

The Elements of Hygiene for Schools. Compiled by Isabel McIsaac, Collaborator of the *American Journal of Nursing*. Cloth. Pp. 172. Price, 60 cents. New York: Macmillan Company, 1909.

This is a presentation of the subject of hygiene in such a way as to be of practical use to pupils in the public schools who will probably have no further opportunity to study the subject. The first chapter is devoted to bacteriology, not only in relation to disease, but to housekeeping, farming and various industries. The hygiene of occupation is discussed at some length. A chapter is devoted to food and in it are discussed the composition of various animal and vegetable foods and the methods of preparing them. Subsequent chapters deal with air, climate, ventilation, etc.; heating and lighting; purification of water; care of sewage and garbage; causes and dissemination of disease; personal, household and school hygiene; disinfection and quarantine. The book is a valuable one and to be commended.

Self-Help for Nervous Women. By John K. Mitchell, M.D., Fellow of the College of Physicians of Philadelphia. Cloth. Pp. 201. Price, $1.00. Philadelphia: J. B. Lippincott Co.

This is a reprint, as stated in the preface, of a series of articles published in 1901 in *Harper's Bazar*, but added to and amended from the suggestions given in the numerous communications received by Dr. Mitchell from correspondents since the first publication. It is not intended for physicians, but it has the medical interest of being the advice to the laity of an experienced practitioner in the treatment of these nervous disorders. There is little or nothing in it that can be criticized by any physician, and some of us might perhaps profit by some little practical hints here and there in its pages. Dr. Mitchell has added his opinion of the so-called Emmanuel movement and of the therapeutic efforts of clergymen in general to the original material of his chapters. He says, in this connection, that while, in his experience, their efforts to afford assistance, in cases in which the nervous sufferers have been referred to them, have as often as not been unsuccessful, the only religious sect in which he has not met these cases is that of the Quakers. This, considering the opportunities for observation he must have had, is of interest. He attributes this to the cultivation of emotional control among Quakers, but it may also be due, it seems to us, to a natural and artificial selection process that has weeded out those who would be most subject to the forms of abnormal mentality here described.

Treatment of the Diseases of Children. By Charles Gilmore [illegible] iseases of Children in the New York [illegible] nd Hospital. *Edition 2. Cloth.* Pp. [illegible] Price, $5. Philadelphia: W. B. Saunders Co., 1909.

The natural assumption of meritorious qualities in a book which has reached a second edition will not be reversed by an examination of this work. It is intended especially for practitioners and is full of suggestions and details which can not fail to make it useful to every one who has to deal with children, either sick or well.

Nicholas Senn. An Appreciation. Published under the auspices of the Nicholas Senn Club of Chicago. By S. M. Wylie, M.D., Paxton, Ill. Cloth. Pp. 27.

This little book was written, says Dr. Wylie, "in fulfillment of a promise made to him [Senn] many times, a compact, mutually agreed on, whereby one of us, God alone knew which, was to perform this service for the other." While in no sense a biography, yet many interesting facts of a biographic nature are given—touches that make the dead surgeon live again. By those who, like Dr. Wylie, were close personal friends of Dr. Senn as well as by those who, while unacquainted with him, yet entertained the highest respect for him both as a man and as a surgeon, this little "appreciation" will be read with pleasure and interest.

Festskrift vid Tuberkulos-Konferensen I Stockholm, 1909. Paper. Pp. 136, with illustrations. Utgifven af Svenska Nationalföreningen Mot Tuberkulos.

Although this pamphlet has a Swedish title, not difficult to understand, that language is entirely avoided in the text; the articles being printed in German, French or English. They cover a considerable number of subjects, relating to the campaign against tuberculosis in Sweden. The first is a general review of the activity of the Swedish National Association against Tuberculosis from 1904 to 1908, in German, by B. Buhre. Next follows an account of the institutional treatment of tuberculosis, comprising two articles, one in French by J. G. Edgren, and the other in English by S. Carlsson. Other articles deal with the sale of charity stamps, the occurrence of tuberculosis in public schools, social hygienic experiments, bovine tuberculosis, and an epidemic of consumption in the commune of Orsa. The book will prove of great interest to those engaged in the campaign against tuberculosis.

Medical and Surgical Report of the Presbyterian Hospital in the City of New York. Vol. VIII, December, 1908. Edited by John S. Thacher, M.D., and George Woolsey, M.D. Boards. Pp. 371, with illustrations.

This report consists mainly of papers by members of the hospital staff, usually reprinted from medical journals. An interesting feature described by W. P. Northrup is the open-air roof-wards which have been established through the generosity of Mr. and Mrs. W. K. Vanderbilt. Experience has shown that for day and night continuous treatment the open roof-wards have done better service than balconies. The volume contains a number of valuable papers which reflect credit on both authors and the institution.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BARTLETT METHOD OF PREPARING CATGUT

To the Editor:—Please publish in The Journal the formula used in preparing catgut by the Bartlett method.

P. H. Provandie, Melrose Highlands, Mass.

Answer.—The following is the method advised by Dr. Willard Bartlett:

The strands are cut in convenient length, say 30 inches, and made into little coils about as large as a silver quarter. These coils are then strung like beads on a thread so that the whole quantity can be conveniently handled by simply grasping the thread. The string of catgut coils is dried for one hour at a temperature of 180 F. and then for a second hour at 220 F., the change in temperature being accomplished gradually. The catgut is then placed in liquid petrolatum, where it is allowed to remain until perfectly clear, in the sense that the term is used in the preparation of histologic specimens. This is usually accomplished in a few hours, though it has been Bartlett's custom to allow the gut to remain in the oil over night. The vessel containing the oil is next placed on a sand-bath and the temperature raised during one hour to 320 F., and this temperature is maintained for a second hour. By seizing the thread with sterile forceps the catgut is lifted out of the oil and placed in a mixture of iodin crystals, 1 part, in Columbian spirits, 100 parts. In this fluid it is stored permanently, and is ready for use in twenty-four hours; the thread is then cut and withdrawn. Thorough preliminary drying is essential; success is only possible when this is carried out in a very dry room and preferably in dry weather. Dr. Bartlett now stores it in a 1 to 1000 iodin solution in Columbian spirits (methyl-alcohol, 97 to 98.5 per cent.).

UHLENHUTH'S METHOD OF BLOOD DIFFERENTIATION

To the Editor:—Please inform me through the columns of The Journal, the full technic of Uhlenhuth's method of blood differentiation, as used in medicolegal work. B. R. LeRoy, Athens, O.

Answer.—The following is the technic as described by Peterson and Haines, in their "Text-Book of Legal Medicine and Toxicology," Vol. ii, p. 751: The method of humanizing a rabbit is to inject into the peritoneal cavity about 10 c.c. of human blood serum at intervals of two or three days until the rabbit has received 6 or 8 injections. The rabbit should be allowed to rest about a week after the last injection. The blood serum for performing the test may then be obtained either by killing the animal by bleeding it from one of the large vessels, or without killing the animal by removing a little blood from one of the large veins of the ear. The blood thus collected should be placed in a cool place and allowed to coagulate. The serum that separates from the clot may be used for performing the test.

The blood to be tested should be prepared as follows: If it be fresh blood, it should be diluted about 1 to 100 with normal salt solution. Thus diluted, it should have a light-pink color, and this diluted solution, if not perfectly clear, should be allowed to settle until it is clear, and the clear, supernatant fluid decanted into another test-tube. If the blood to be tested is a dry blood-stain, a little of it may be scraped off with the point of a knife on to a watch-glass, if the stain be on some hard surface so that the blood has not penetrated into the substance of the material. If the blood-stain be on cloth into which the blood has soaked, it is necessary to cut out a few threads and transfer them to a watch-glass. These fragments of dried blood should then be treated with two or three drops of distilled water until the soluble portion of the dried blood has been dissolved. The clear solution should then be transferred carefully to a very narrow test-tube, and to this should be added an equal volume of double normal salt solution. The clear fluid thus obtained either by diluting fresh blood or by dissolving the blood serum from the dried blood-stain is then tested by adding to it a few drops of the serum obtained as above described from the humanized rabbit. If the solutions contain human blood serum, there will occur an immediate cloudiness that gradually increases, so that there is a distinct precipitation within one-half hour after the addition of the serum from the humanized rabbit. It is better often to allow the antiserum to flow down the side of the test-tube, so as to form a separate layer under the solution to be tested, in the same way that we add nitric acid to urine in testing for albumin. In this case the cloudiness and precipitate may be seen very distinctly in the zone at the point of contact of the two fluids. The precipitate occurs best when the mixture is kept at a temperature of about 37° C.

Ewing has shown that, in applying the serum test, it is important that the solution of the blood under examination be not too strong; if it is too concentrated, the blood of some of the lower animals may react to a greater or less degree. At a dilution, however, of at least 1 to 50 the blood of lower animals fails to give a reaction, and the test becomes a specific one for human blood. Dilution of the serum is even better than dilution of the blood.

TUBERCULOSIS OF FEMALE GENITALIA

To the Editor:—Please give me references to literature on tuberculosis of the female genitalia. A. Belitz, Milwaukee, Wis.

Answer.—The following articles may be referred to:

Martin, A. Genital Tuberculosis, *Berl. klin. Wchnschr.*, Jan. 30, 1908; abstr. in The Journal, Feb. 22, 1908, p. 650.

Simmonds, M.: Tuberculosis of the Female Genitalia, *Arch. f. Gynäk.*, lxxxviii, No. 1; abstr. in The Journal, May 22, 1909, p. 1725.

Blau, A.: Origin and Spread of Tuberculosis in the Female Genital Tract. (Ueber die Entstehung und Verbreitung der Tuberkulose im weiblichen Genitaltrakte.) Verlag von S. Karger, Karlstrasse 15, Berlin, Germany.

TRAUMATIC NEPHRITIS

To the Editor:—Please give references to literature on traumatic nephritis (Bright's disease).

A. J. Crowell, Charlotte, N. C.

Answer.—The following articles have appeared since 1904:

Oberndorfer, S.: Post-Traumatic Nephritis, *Münchener medizinische Wochenschrift*, l, No. 50; abstracted in The Journal, Jan. 16, 1904, p. 210.

Klippel and Chabrol, E.: Traumatic Nephritis with Unilateral Edema. *Presse Médicale*, April 14, 1909; abstracted in The Journal, May 29, 1909, p. 1799.

ACETONE TREATMENT OF INOPERABLE CANCER OF THE UTERUS

To the Editor:—Please give me reference to the acetone treatment of inoperable cancer of the uterus.

M. Iverson, Stoughton, Wis.

Answer.—The acetone treatment for inoperable cancer of the uterus is described by G. Gellhorn, St. Louis, in The Journal, April 27, 1907, p. 1400. Further reports by him have appeared in the *St. Louis Medical Review*, November, 1907, and in the *Münchener medizinische Wochenschrift*, Dec. 17, 1907.

The same treatment is referred to favorably by F. J. Taussig of St. Louis, in the *Interstate Medical Journal*, February, 1909.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Regular, Little Rock, November 9. Sec., Dr. F. T. Murphy, Brinkley.
Connecticut: Homeopathic, New Haven, November 9. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.
Connecticut: Regular, City Hall, New Haven, November 9-10. Sec., Dr. Charles A. Tuttle, 196 York St.
Florida: Jacksonville, November 10-11. Sec., Dr. J. D. Fernandez.
Illinois: Coliseum Annex, Chicago, October 20-22. Sec., Dr. J. A. Egan, Springfield.
Louisiana: Homeopathic, New Orleans, November 1. Sec., Dr. Gayle Aiken, 1102 St. Charles Ave.
Maine: Portland, November 9-10. Sec., Dr. Frank W. Searle, 806 Congress St.
Massachusetts: State House, Boston, November 9-11. Sec., Dr. E. B. Harvey, Room 159, State House.
Nebraska: Senate Chamber, State House, Lincoln, November 10-11. Sec., Dr. E. Arthur Carr, 141 South Twelfth St.
New Jersey: State House, Trenton, October 19-20. Sec., Dr. E. L. B. Godfrey, Camden.
Nevada: Carson City, November 1. Sec., Dr. S. L. Lee.
Texas: Levy Bldg., Greenville, November 9-11. Sec., Dr. M. E. Daniel, Honey Grove.
West Virginia: Chancellor Hotel, Parkersburg, November 9-11. Sec., Dr. H. A. Barbee, Point Pleasant.
Wyoming: Laramie, October 20-22. Sec., Dr. S. B. Miller.

Better Conditions at the University of Vermont

The University of Vermont College of Medicine, Burlington; hereafter will be entirely under the control and management of the trustees of the university, according to an editorial in the *Vermont Medical Monthly* for August. There has been a partial control by the university for several years, but all financial obligations had to be met by the faculty of medicine. At the last meeting of the Vermont legislature an annual appropriation of $10,000 was voted to the university in aid of medical education, which made it possible for the university to assume the financial responsibility of the department, collecting all fees and paying all bills, including salaries. The College of Medicine of the University of Vermont well deserved this additional assistance and it means better things for medical education in that state. The medical faculty has voted to increase the preliminary requirement to one year of college work, including courses in physics, chemistry and biology, the increase to become effective in 1912.

Damages Awarded Against a Medical College

It is reported in the *Texas State Journal of Medicine* that Dr. R. L. Charlton was lately awarded judgment in the district court of Dallas county, Texas, for $1,000 damages against the College of Physicians and Surgeons, formerly the Bell Medical College, but in attempting to enforce the order the sheriff could find no property out of which to obtain the money. This information is interesting since it confirms the Texas State Board of Medical Examiners in their withdrawal of recognition from this medical college on the ground that it was not properly equipped to furnish medical education.

University of Southern California Has a New Medical Department

When the former College of Medicine of the University of Southern California became the Los Angeles Medical Department of the University of California the former university was left without a medical department. Recently, however, the College of Physicians and Surgeons of Los Angeles was taken over and made an integral part of the University of Southern California. It is stated that an enlargement of the medical course will follow the merger.

Texas June Report

Dr. M. E. Daniel, secretary of the Texas State Board of Medical Examiners, reports the written examination held at Cleburne, June 22-24, 1909. The number of subjects examined in was 12; percentage required to pass, 75. The total number examined was 175, of whom 150 passed, 19 failed, and 6 withdrew. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
College of Physicians and Surgeons, San Francisco	(1902)	80.6
Birmingham Medical College	(1908)	77
University of Arkansas	(1901)	83.9

Maryland June Report

Dr. J. McP. Scott, secretary of the Maryland State Board of Medical Examiners, reports the written examination held at Baltimore, June 22-25, 1909. The number of subjects examined in was 9; percentage required to pass, 75. The total number of candidates examined was 121, of whom 100 passed and 21 failed. Twenty-two candidates were licensed through reciprocity and 5 under exemption clauses and by special examination. The following colleges were represented:
